Number 1

ACUTE APPENDICITIS COMPLICATING THE ACUTE INFECTIOUS DISEASES OF CHILDHOOD*

KNOWLES B. LAWRENCE, M.D.,† AND GEORGE W. WARING, JR., M.D.‡

BOSTON

ACUTE appendicitis in children displays certain features in its pathology, clinical course, diagnosis and treatment, which vary considerably from those of the disease in adults. The development of appendicitis during the course of one of the acute infectious diseases or in a child exposed to them further complicates the problem.

It seems to be commonly accepted opinion that certain of the contagious diseases, such as measles, tend to be complicated by a higher than normal incidence of appendicitis, that the diagnosis of acute appendicitis is apt to be rendered more difficult or masked by the presence of one of these contagious diseases, and that the mortality and morbidity of acute appendicitis is higher when so complicated than that of appendicitis occurring alone.

Most reviews of the problem of appendicitis give little statistical consideration to these aspects. Ladd and Gross¹ mention an apparently increased frequency of acute appendicitis in children with measles. Babcock² also states that "infections that produce general lymphoid hyperplasia such as measles, scarlet fever — often precede appendicitis." Scott and Ware,³ on the other hand, in a more recent appraisal of appendicitis in children, believe that no causal connection exists between the acute contagions and other upper respiratory infections and acute appendicitis.

A check on the validity of these impressions was undertaken in a study of cases of acute appendicitis in children under twelve years of age seen during a twenty-one-year period, recently ended at the Haynes Memorial, the infectious disease unit of the Massachusetts Memorial Hospitals in Boston. This included a group of 100 consecutive cases in which the appendix was examined

demonstrated some stage of acute appendicitis. In 61 of these the appendix was perforated, and some degree of peritonitis existed. Although sufficient evidence of localization to warrant the use of the term "abscess" was noted in 17 cases, we have found this an unsatisfactory classification because in children appendiceal peritonitis tends to localize poorly. Clinically, they may well be far sicker than the term "appendiceal abscess" suggests when the condition is encountered in an adult, and often

TABLE 1 *Relation Between Type of Appendicitis and Mortality Rate*

TYPE	NO OF CASES	NO OF DEATHS	MORTALITY %
Acute (with no rupture)	35	1	2.8
Acute (with rupture and local or diffuse peritonitis)	61	7	11.5
Pinworms only	2	0	0
Normal appendix	2	0	0
Totals	100	8	
Average			8.0

require as vigorous and prompt treatment as cases without any tendency to localization of the peritonitis. Scott and Ware³ recognized this situation in classifying acute appendicitis at the Children's Hospital in Boston and grouped their cases as "acute, unruptured" and "acute, ruptured with local or diffuse peritonitis." In more than 1300 cases reported by them, perforation of the appendix had occurred in 44.8 per cent, as compared with 64 per cent in our series.

Only 4 cases of the 100 in this group revealed no acute inflammation on microscopical examination. Pinworm infestation was the only finding in 2 of these cases, although the symptomatology and physical findings were those of acute appendicitis. In the remaining 2 cases entirely negative pathological findings indicated errors in the clinical diagnoses.

PATHOLOGICAL FINDINGS

The pathologic changes found in these cases are listed in Table 1. Ninety-six patients (96 per cent)

*From the Haynes Memorial, Massachusetts Memorial Hospitals and the Department of Surgery and Medicine, Boston University School of Medicine.

†Instructor in surgery, Boston University School of Medicine; associate visiting surgeon, Massachusetts Memorial Hospitals.

ASSOCIATION OF INFECTIOUS DISEASES WITH APPENDICITIS

Table 2 shows the distribution of the various infectious diseases associated with acute appendicitis in this series.

Eighty-eight of these children actually had an infectious disease and the remaining 12 had been exposed to or were thought to be in the prodromal stage of one at the time of admission. The three largest and nearly equivalent groups of cases of appendicitis correspond to the three most common diseases: scarlet fever, measles and chicken pox, which accounted for 77 of the 88 actual cases of infectious disease in this series. In Table 2 are listed also the admission totals for the various contagions at the Haynes Memorial over the twenty-one-year

TABLE 2. Twenty-One Year Experience with Appendicitis in 104 Cases (Children under Twelve Years)

DISEASE	CASES OF APPENDICITIS (HAYNES MEMORIAL)	TOTAL CASES OF INFECTIOUS DISEASE	
		ALL IN HAYNES MEMORIAL	IN ACUTE APPENDICITIS
Scarlet fever	2	12,192*	231
Measles	2	11,451*	84
Chicken pox	50	60	254
Pertussis	11	50	11
Rubella	—	—	—
Mumps	—	104	177
Miscellaneous	4	—	—
Total	104	—	—

*This figure represents 5 per cent of all reported cases of scarlet fever in Massachusetts.

†These children, although exposed, failed to develop a clinical case of disease. Four children had two of the common infectious diseases.

period 1927 to 1948. The experience with scarlet fever is revealed as much greater than that with any other disease because it has been the policy of the Massachusetts Department of Public Health to encourage routine hospitalization of all patients with scarlet fever whenever possible.

The 23 cases of appendicitis occurring in the large group of 12,192 patients with scarlet fever admitted to the hospital represented an incidence of only 0.2 per cent, which was probably a fair sample of the statewide experience. It is interesting to note that the approximate incidence of appendicitis in all children under the age of ten years calculated from mortality tables for the year 1947 in Massachusetts was also 0.2 per cent.*

Total admission figures for measles, chicken pox, pertussis and mumps at the Haynes Memorial are seen as relatively small compared with the total reported cases for the state (data supplied by the Massachusetts Department of Public Health) since admissions for these diseases were chiefly because

of complications. Similar incidence rates for appendicitis occurring in these diseases, therefore, cannot be calculated on any sound statistical basis, although it seems apparent from a study of Table 1 that such rates would probably be no higher than those for appendicitis in scarlet fever.

Our interpretation of these data is that, contrary to traditional opinion, children with scarlet fever and other common contagious diseases show no greater tendency to the development of acute appendicitis than otherwise normal children do.

INCIDENCE OF INFECTIOUS DISEASES ON DIAGNOSTIC ACCURACY

The diagnosis of acute appendicitis in a child already ill with an infectious disease may be a very difficult one to make, as every physician who faces this problem will testify. Statistically, the effect of such diseases on the accuracy with which co-existing appendicitis could be diagnosed prior to hospital admission probably is best reflected in certain data presented in Table 1. Sixty-one per cent of the acutely inflamed appendixes in our series were found to have ruptured, whereas only 44.8 per cent were ruptured in the Children's Hospital series. This higher incidence of rupture apparently cannot be attributed to a predominance of younger patients since only 41 per cent of the ruptured appendixes in our series were found in children under the age of six years, whereas the figure derived from the Children's Hospital series was 53 per cent. Further analysis of the data suggests also that our high percentage of perforation cannot be explained by a postulated acceleration of the appendiceal inflammation by the infectious disease. The average period of delay from onset of symptoms to hospitalization for simple acute appendicitis was 1.4 days, but for ruptured appendix with local or generalized peritonitis, it was 3.1 days. These delays are essentially the same as those encountered in children with appendicitis uncomplicated by such diseases, as comparison with figures derived from the large series at the Children's Hospital will reveal. Calculations from the data of Scott and Ware³ show average delays of 1.5 and 3.4 days for the corresponding stages of appendicitis. Undoubtedly, masking symptoms and signs such as abdominal pain, fever, nausea and vomiting and respiratory complaints, which are often part of the presenting picture of the acute contagion, have made the diagnostic problem more difficult for the referring doctors. The telltale signs of peritonitis, when these developed, usually could be distinguished readily enough from those of the contagion so that the delay in these cases after rupture was not of unusual duration. Five children, however, all with ruptured appendixes, were referred to the hospital without any suggestion of this diagnosis but merely because the courses of their infectious diseases seemed unfavorable.

*This calculation is based on an assumed mortality rate of approximately 5 per cent for acute appendicitis in this age group.

After admission to the hospital diagnosis was made earlier, of course, by more elaborate facilities, in addition to the fact that in most cases, signs were better established. It is not surprising, then, that a diagnosis of acute appendicitis leading to early operation could be made promptly after admission by the resident staff and consultants in 84 of 100 cases. In an additional case, operation was deliberately delayed for eighteen hours in an attempt to improve the condition of the critically ill and toxic child. Operation was delayed for twelve hours or more in 14 children because of uncertainties in diagnosis, but in only 9 of these was a sufficiently serious appendicitis found to have made this delay of any hazard to the patient. The entire series included only 1 case in which death resulted after continued failure to diagnose a ruptured appendix clinically in the hospital. These statistics, however, fail to indicate adequately the very real difficulty encountered occasionally at the Haynes Memorial in making the diagnosis of appendiceal peritonitis in very young children.

An undetermined number of children, possibly 50 or more, were admitted during the same period covered by this study with a question of acute appendicitis that could not be confirmed by further observation and study at the hospital. Lymphadenitis or lymphoid hyperplasia, acute enteritis, mumps oophoritis, pancreatitis, referred pain and even constipation were variously thought to account for the clinical pictures simulating appendicitis in these cases.

CASES WITH DELAY IN HOSPITAL DIAGNOSIS

As noted above, in 9 children with established and serious appendicitis, operation was delayed more than twelve hours from time of admission owing to difficulties in diagnosis. In 1 of these, which resulted in death, there was a probable delay of four days after the onset of appendicitis in a child who was convalescing in the hospital from scarlet fever. When actual pain and tenderness developed, operation was performed immediately, and a small abscess was encountered. The child did well initially but died thirty days later from meningitis and septicemia, which did not seem to bear any direct relation to the appendicitis. Ruptured appendixes and varying degrees of peritonitis were found in half (4 cases) of the other 8 patients in this group. Five of these children had active chicken pox. None of this group of 8 died, however.

In summary, it seems fair to say that the diagnosis of acute appendicitis in the hospital was made somewhat more difficult by the coexistence of the infectious diseases. Serious delays in diagnosis occurred in 9 cases or about 10 per cent of the total, several patients being very sick children and difficult therapeutic problems. Fortunately, there was only 1 fatal case in this group. No data

are available for comparison on the percentage of diagnostic delay in children with appendicitis uncomplicated by other diseases although it must be appreciable.

ANALYSIS OF DEATHS

There were 8 deaths in the whole series of 100 cases. One of these, mentioned above, resulted from a diagnostic error. This occurred in C M, a three-year-old girl, who had been exposed to pertussis and who entered the hospital on November 6, 1937,

FIGURE 1. Clinical Course in a Thirty-Four-Month-Old Girl with Undiagnosed Appendiceal Peritonitis

after forty-eight hours of fever and vomiting in a very toxic state with distended abdomen and clinical signs of pneumonia. Although she was observed carefully and seen by two surgical consultants, the clinical findings never seemed adequate to warrant a diagnosis of acute surgical condition of the abdomen (Fig 1). Conservative therapy, which did not include sulfonamides was ineffectual, and the child died on the seventh day after admission, autopsy revealed a ruptured appendix and generalized peritonitis but no pneumonia.

The other 7 deaths in this series came after operation. In 1 of these children (referred to above) death occurred on the seventy-eighth hospital day being due to a streptococcal meningitis following bilateral mastoiditis, this case, in all fairness, could be excluded from the deaths caused by appen-

diectis Five other children died after operation, apparently from peritonitis, including the child who was given conservative therapy eighteen hours before operation, in an effort to improve his general condition. It seems significant that all 5 of these patients were treated in the years prior to so-called "modern therapy" when adequate fluids and electrolytes were not administered parenterally, stomach and intestinal intubation was not employed, and there was no chemotherapy. The descriptions of these cases were those of intractable ileus, dehydration and toxieity. Only 1 child among the 7 dying postoperatively was seen recently enough for modern supplementary therapy. In this patient, a girl with rubella, an appendectomy was performed for acute appendicitis without perforation, but an intractable ileus and hyperpyrexia developed postoperatively. She failed to respond to parenteral administration of fluids, sulfonamide therapy and gastric intubation, and although no autopsy was obtained, it was postulated that there might have been a "blow-out" of the appendiceal stump postoperatively or some other accidental cause of peritonitis.

CLINICAL OBSERVATIONS

Diagnosis

Of the several symptoms that suggested acute appendicitis in children, *pain* was the most obvious and the presenting symptom in 78 per cent. This was a right-sided or right-lower-quadrant pain in most cases. An initial periumbilical or epigastric pain was complained of less often than in adult patients. Other symptoms such as vomiting, fever and changes in bowel habits were reported frequently, but are such common symptoms of scarlet fever, measles and pertussis that they seemed to have no specific value in the differential diagnosis.

Certain physical signs seem to have been even more helpful than the history of pain in our series. *Local tenderness* over the area of the appendix was observed in the majority of children with acute appendicitis. *Spasm* was an informative sign at times in older children but rarely in very young children, probably because of voluntary splinting, crying and poor co-operation in general. We have listened carefully for intestinal peristalsis in recent years, and this has proved quite helpful at times in differentiating acute appendicitis from acute enteritis. Peristalsis was usually normal or diminished to auscultation in appendicitis, but almost invariably hyperactive in acute enteritis. The production of pain by coughing and rebound tenderness, probably explainable as resulting from the agitation of inflamed peritoneal surfaces, have been quite impressive and helpful diagnostically in some of the older children. Abdominal distention and ileus (in the absence of obvious reflex sources of this disturbance, such as pneumonia) was found

frequently in appendiceal peritonitis and was, in fact, suggestive of this diagnosis. Rectal examination has been of little help to us in the diagnosis of acute appendicitis except for the identification of a palpable mass in the pelvis. After one or more digital rectal examinations small children have become so apprehensive and poorly relaxed that it has been impossible to localize tenderness rectally.

The body temperature and the pulse rate have been influenced sufficiently by the contagious diseases present in many cases to be of little help in the diagnosis of the acute appendicitis.

The white-cell count and the differential count have also been confusing at times. In several cases of acute appendicitis developing in children with measles, for example, low total white-cell counts with mild neutropenia were found.

DISCUSSION

Surgical Management

It seems generally agreed that the diagnosis of acute appendicitis without perforation in a child, as well as in an adult, calls for early operation. This should never be so rushed, however, that sufficient time is not taken to restore disturbed fluid and chemical balances and to place the child on stomach drainage if there has been vomiting or evidence of ileus. Scott and Ware² and others^{1, 4, 5} emphasize the need of this preparation. The co-existence of one of the infectious diseases does not alter this indication for early surgery in our experience, except that the child may require a little longer preoperative preparation because of exposure to a longer period of toxieity and dehydration.

The time of operation is undoubtedly a more debatable question in cases of ruptured appendix with peritonitis. Conservative management of appendiceal peritonitis has proved valuable in many adult cases in the past, although undoubtedly the utilization of the more modern methods of treatment, particularly antibacterial therapy, must be altering the picture a great deal, permitting earlier surgery. We believe that continued conservative treatment of appendiceal peritonitis rarely is indicated in children—a belief based on personal experience as well as the testimony of several others.^{1, 3, 4}

For various reasons localization of the peritonitis cannot be relied on as effectively in children as in many adults. Anatomically, children do not have a sufficiently developed omentum and other peritoneal appendages available to aid in localization of a peritonitis. In addition, the appendix itself is far larger and longer in relation to the intestines and peritoneal structures than that in the adult, and the cecum often seems more mobile, creating greater potentialities of contamination by repeated leakage of pus and bowel content from a perforated appendix.

From a therapeutic point of view small children seriously ill with appendiceal peritonitis may be very difficult to handle. Fluid and electrolyte depletions develop rapidly. The veins are difficult to find and to keep cannulated for the necessary administration of replacement fluids. It is difficult to keep gastrointestinal tubes down and properly functioning.

A recent case illustrates the failure of conservative handling of appendiceal peritonitis despite all modern therapeutic efforts.

R. McA, a 2-year-old boy, was admitted to the Haynes Memorial Hospital in September, 1947, with a diagnosis of poliomyelitis, which was confirmed by spinal-fluid findings and clinical observations. For the first 2 days in the hospital his course was approximately that of other patients being treated at the same time. He had only a slight fever and little toxicity but presented a partial paralysis of the trunk and extremities. Two days after admission abdominal distention, with a quiet abdomen and some temperature and pulse rise, developed. Physical and x-ray signs of bronchopneumonia were present. He did not complain of specific abdominal pain, and there seemed to be no definite tenderness. The distention became more severe, and it was thought that he probably had the type of paralytic ileus not infrequently associated with pneumonia and sometimes with severe poliomyelitis. A Miller-Abbott tube was passed, adequate

FIGURE 2 Clinical Course in a Two-Year-Old Boy with Poliomyelitis and Perforated Appendix

fluids administered parenterally and intramuscular injection of penicillin started. The patient improved somewhat but had a recurrence of distention in 24 hours and again became very toxic. On the 4th day after the onset of the original distention a mass could be felt in the right lower quadrant of the abdomen. He was seen in consultation by one of us (A. B. L.), and it was thought that he had peritonitis from a ruptured appendix, with partial localization. Operation was performed promptly through a small McBurney incision. A large collection of pus was drained from the upper portion of the pelvis and the right lower quadrant, and the poorly formed walls of the abscess cavity, formed largely by adjacent bowel, collapsed. The appendix lay directly beneath the incision and was removed very simply after ligation of its base. Only the abdominal wall superficial to the peritoneum was drained. Postoperatively, the child improved dramatically. The temperature fell to practically normal in less than a day, he had spontaneous bowel movements about 2 days postoperatively and improved rapidly from then on. The clinical course is demonstrated in Figure 2.

In this case dramatic improvement and recovery followed the drainage of the septic process and removal of the appendix, although until that time the patient was getting rapidly and steadily sicker despite heavy doses of penicillin and streptomycin, adequate fluids, transfusions, oxygen, gastrointestinal intubation and other supportive therapy.

It has been our general experience in cases of ruptured appendix with peritonitis in children that early removal of the appendix, as a source of continuing contamination, with aspiration of available pus, when supplemented by antibacterial and other appropriate therapy, almost always results in prompt improvement in the patient's condition and in recovery. Figure 3 shows the temperature chart

FIGURE 3 Clinical Course in a Six-Year-Old Boy with Chicken Pox and Appendiceal Peritonitis

and clinical data in J. N., a six-year-old boy, seen in July, 1947, whose course was typical of cases of this sort.

Anesthesia

Inhalation ether has been the preferred anesthetic, since this seemed easiest to administer to small children and probably the safest, yielding adequate relaxation when properly given. Spinal anesthesia has been used in a few older children.

Surgical Technique

The McBurney incision has been used almost exclusively in the past three years and has proved generally satisfactory in appendicitis in children, simply for removal of an acute appendix or when the condition is complicated by peritonitis or abscess. This incision has provided adequate access to the appendix without great disturbance of the intestines, and the spreading of contaminated material. It is interesting to note that when the type of incision was recorded for cases of perforated appendix in this series, 36 rectus incisions were

made with 1 case of extensive wound slough and 1 of serious wound infection, whereas there was only 1 deep wound infection in 21 McBurney incisions. In the infected McBurney incision the abdominal wall had not been drained despite contamination by intraperitoneal pus. It is only fair to say that most of the McBurney incisions were made during the era when chemotherapy was administered. We follow the practice of doubly ligating the base of the appendix and tying over it a portion of meso-appendix or any epiploic fat tab locally available and have had no proved case of leakage from the stump or other stump complications. We do not consider it necessary or desirable to drain the peritoneal cavity, except in the rare case in which it may not be possible to remove the appendix or to secure its base properly, or when a great deal of necrotic material in relation to an abscess is encountered. In the last three years covered by this study all children with appendiceal peritonitis, 12 in number, were treated in this way without intraperitoneal drains, and in no case was there any extension or failure of resolution of the peritonitis or any case of subsequent intraperitoneal abscess that, it seemed to us, might have been prevented by the use of a drain. Undoubtedly, the vigorous use of antibacterial drugs during this period has helped in the sterilization of the peritoneal exudate. There have been 2 cases of cul-de-sac cellulitis in this recent group, and both of these resolved completely under medical management. We have found it expedient to place a soft-rubber tissue drain down to the peritoneum in all cases of peritonitis. The peritoneal fatty tissue appears to be quite vulnerable to infection, and a deep abdominal-wall abscess with cellulitis is likely to originate in this area if this drainage is omitted.

Antibacterial-Drug Therapy

The sulfonamide drugs, penicillin and streptomycin undoubtedly have been valuable in assisting the localization of appendiceal peritonitis and the control of complications, such as pneumonia. In a group of 26 children with appendiceal peritonitis, prior to the advent of this treatment, there were 5 deaths, all due to sepsis, whereas in 21 recent cases, treated in the era of antibacterial drugs, only 1 death occurred. Sulfanilamide was the only form of chemotherapy available for administration to this particular patient. Although sulfanilamide was implanted intraperitoneally in several cases of this series, we now prefer to administer the sulfonamide drugs, when indicated, by the intravenous or oral

routes, believing that equivalent or better control of peritonitis can be obtained with greater safety. Much credit for the striking improvement under chemotherapy, however, must be given to the other aspects of modern supportive therapy in such sick surgical patients. Our present policy is to use heavy penicillin therapy by frequent intramuscular administrations supplemented by sulfadiazine or streptomycin in the more toxic children with peritonitis, particularly if the cultures demonstrate susceptible organisms.

SUMMARY AND CONCLUSIONS

An analysis of the experience with acute appendicitis at an active infectious-disease hospital indicates that there is no apparent predisposition to the development of acute appendicitis in children with the common infectious diseases.

The diagnosis of acute appendicitis was rendered somewhat more difficult by the coexistence of other diseases, but not to the point where any large number of diagnoses were missed or necessary surgical treatment postponed beyond the critical period.

A much higher incidence of ruptured appendix with peritonitis was found in this series (64 per cent) than in a group from a large children's clinic admitting very few patients with infectious disease (46 per cent). It seemed likely that this difference was due to greater difficulties in diagnosis during the period before admission to the hospital.

The mortality of 8 per cent in this series of 104 cases is high. In our opinion, it was attributable only in small part to diagnostic difficulties and the complications imposed by the coexistence of the infectious diseases. In the twenty-one-year period covered, 7 of the 8 deaths occurred before the use of modern treatment, including chemotherapy, parenteral administration of fluids, intubation and transfusions. These deaths were due to sepsis and might have been prevented had such therapy been available.

We are indebted to Dr. Louis Weinstein, physician and chief of service, Haynes Memorial Hospital, for his co-operation and helpful criticisms in the preparation of this paper.

THE EVOLUTION OF INTERCAPILLARY GLOMERULOSCLEROSIS*

HARRY A DEROW, M D † AND MONROE J SCHLESINGER, M D , P H D ‡

BOSTON

IN 1936, Kimmelstiel and Wilson¹ described a diffuse, microscopic lesion in the kidneys of 8 middle-aged and elderly diabetic patients with hypertension, profuse albuminuria and generalized edema. The abnormality was termed "intercapillary glomerulosclerosis" and consisted of striking changes in the intercapillary tissue characterized by large hyaline masses confined to the centers of the glomeruli or glomerular lobules. Less severe degrees of this hyalinization were also reported. These observations have been confirmed and ex-

CASE REPORT

R S (B I H 30736), a 61-year-old married woman, had been told in 1935 by her family physician that her blood pressure was elevated. In March, 1936 she complained of loss of weight, weakness, pruritus vulvae, polyuria and polydipsia of 9 months' duration and of repeated attacks of gall-bladder colic without jaundice for 15 years. The blood pressure was 170/106. The urine gave a +++ test for sugar and contained no albumin. In April she was hospitalized for regulation of the diabetes mellitus. The left kidney was palpable; retrograde pyelography revealed a "large cyst in the lower pole." Intravenous cholecystography revealed no filling. The blood pressure was 166/100 and dropped to 110/70 during the rest of her hospital stay.

tended by many authors,^{2,5} and the subject has recently been reviewed by Kimmelstiel and Porter.⁹ The available published data are inconclusive concerning the period necessary for the evolution of the lesions of intercapillary glomerulosclerosis from their inception to the advanced stage. An opportunity was recently provided to study a patient who had had diabetes mellitus for the last eight years of her life. Four years before death a nephrectomy had been performed for a suspected neoplasm. Two years before death—that is six years after the onset of diabetes—massive albuminuria developed. Comparative histologic study of the surgically removed kidney and that obtained at autopsy provided a basis for elucidating the development of the renal disorder and the correlation of the latter with the clinical picture.

The diabetes was readily controlled with moderate doses of regular insulin. The urinary findings are recorded in Table 1. Cholecystectomy was performed and cholelithiasis and chronic cholecystitis were found. After discharge the patient did well on a diet and moderate doses of protamine zinc insulin. Repeated urine examinations revealed no albumin. In April 1940, because the left kidney had increased in size, a renal neoplasm was suspected and nephrectomy was performed. The diabetes remained well controlled. The blood pressure ranged between 110/70 and 150/80. Two urine examinations revealed no albumin. At operation a grape-fruit-sized renal cyst was found; the kidney without the cyst weighed 155 gm. The significant microscopic findings are listed in Table 2. Thereafter she again did well until December when she was readmitted for several days because of an upper respiratory infection. Three urine examinations revealed no albumin. An electrocardiogram was normal. The diabetes remained readily controlled with diet and small amounts of insulin. In February, 1941, for the first time she showed early bilateral lenticular opacities. The disks and vessels were normal; there were no hemorrhages or exudates. In June, 1941, bilateral high ligation of the saphenous veins was performed for varicose veins. The blood pressure was 160/86. Again, the urine was normal (Table 1). Three weeks postoperatively, after bleeding in the incision in the left groin, the patient experienced fever, chills and severe localized inflammation for which she was again hospitalized (Table 1). Chills and fever continued during the 1st week, and blood cultures revealed *Staphylococcus albus*. For the first time

albuminuria was noted. After 5 days of oral and parenteral administration of sulfathiazole, the drug was omitted because of microscopical evidence of hematuria. On August 6, a large abscess in the left groin was incised and drained, the pus revealed *Staph. albus*. On August 8 perivascular abscesses of the left thigh and calf were drained, and the left greater saphenous vein was excised. She felt well until August 30, when chills, fever and tenderness in the left flank indicated sepsis. Sulfadiazine was administered for 1 month. Albuminuria had disappeared, and except for occasional microscopical evidence of hematuria and slight glycosuria the urine was normal. On September 8 an abscess in the posterior aspect of the left thigh was incised and drained, and 3 days later the left common iliac vein was ligated after a septic clot was found in the left external iliac vein. The septic course continued and bilateral necrosis of the heels and a decubitus ulcer of the sacrum developed. Sulfadiazine was again given for 2 weeks, during which albuminuria and

between the disk and macular region was a large, homogeneous, yellowish-white area of about 4 disk diameters over which the vessels were not seen. On May 13 further reduction in vision was found (4/200 on the right and 3/200 on the left).

After her discharge from the hospital in May, 1942, the diabetes was mild and insulin was unnecessary. Six months later massive albuminuria first appeared (Table 1). In June, 1944, she experienced pain in the left anterior portion of the chest. She was hospitalized on August 5 because of sudden onset of cough, dyspnea, fever, weakness, drowsiness, nausea and vomiting. Examination revealed fever, basal pulmonary rales and a blood pressure of 165/80. The elevated temperature subsided promptly after penicillin therapy. Glycosuria was readily controlled with 20 units of protamine zinc insulin daily. The blood nonprotein nitrogen fluctuated between 46 and 79 mg per 100 cc. The serum protein was 5.9 gm per 100 cc. An electrocardiogram revealed normal

hematuria were absent. After excision of the necrotic tissue over the sacrum the patient became afebrile, and the ulcers of the heels disappeared. On January 24, 1942, an abscess under the nail of the right great toe was drained and healed slowly. Bilateral foot drop developed, the knee jerks, ankle jerks and vibration sense were absent. Insulin was not necessary during the 10-month period of hospitalization. She was discharged on May 1, 1942.

She was checked at monthly intervals during the remainder of 1942, and occasionally thereafter. Her vision was 20/100 on the right and 20/40 on the left. The neurologic manifestations showed little improvement. The sacral lesion responded slowly but was not completely healed until September 21, 1943. Throughout this period, the blood pressure was approximately 160/90.

Gradually, her vision became impaired until on April 22, 1944, it was 8/200 on the right and 4/200 on the left. Numerous small lenticular and vitreous opacities were seen. Ophthalmoscopic examination revealed for the first time slight blurring of both disk margins and small hemorrhages intermingled with clump-like, white exudates of different sizes between the disks and macular regions in the left fundus

rhythm, with a rate of 65, ventricular premature beats, a small Q wave in Lead 3 and inverted T waves in Leads 2, 3 and 4. Lethargy, incontinence of urine and recurrence of sacral decubitus ulcers characterized the remainder of her hospital course, and she died on August 20.

Autopsy (A44-77), performed 4½ hours after death, showed minimal edema of the ankles. No fluid was present in the pleural or peritoneal cavities.

The heart weighed 340 gm. The coronary arteries were sclerotic. The left ventricular wall was 1.3 cm and the right 0.5 cm in thickness. At the anterior aspect of the apex of the left ventricle an area of soft myocardium was overlaid by a friable mural thrombus. Microscopical examination of the heart revealed patchy fibrosis throughout the myocardium and an organized endocardial thrombus overlying a completely healed infarct at the apex.

The pancreas was normal on gross examination and microscopically revealed occasional hyaline arteriolar change. The lungs showed patches of bronchopneumonia. The spleen was normal in size and weight and contained a small infarct. The liver and adrenal glands were normal on gross and microscopical examination. The duodenum ex-

hibited an old ulcer in the first portion. Gross and microscopical examination of the brain revealed moderate atheromatous changes of the arteries and focal areas of encephalomalacia. The aorta and external iliac arteries exhibited moderate atheromatous changes.

The remaining right kidney weighed 200 gm. On gross section, the cortex was pale and measured approximately 7.0 mm in thickness. The line of demarcation between the cortex and the medulla was poorly defined in contrast to the kidney removed 4 years previously, which, except for the cyst, had been essentially normal on gross examination.

Both kidneys were subjected to the same type of microscopical analysis. Sections from both organs stained with methyl-violet and iodine showed no amyloid; sections were also stained with hematoxylin and eosin, eosin and methylene blue and Mallory's aniline blue.

All the glomeruli in the available sections were individually studied. An attempt was made to evaluate the degree to which intercapillary thickening involved each glomerulus. The glomeruli that exhibited one to five or more large (20 to 120 microns in diameter), discrete hyaline globular masses in addition to diffuse thickening of the axis with or without small irregular hyaline masses were considered to have a severe degree of intercapillary glomerulosclerosis. The moderately severe lesions were those in which the glomeruli contained small irregular hyaline masses (less than 20 microns in diameter) in the midst of diffuse thickening of the axis of the glomerulus. The mild lesions consisted of only a diffuse thickening of the axis of the glomerulus. The extent of the involvement was evaluated by determination of the percentage of glomeruli exhibiting the lesions described above. The percentage showing complete hyalinization and that revealing afferent arteriolar hyalinization, capsular thickening and capsular adhesions were also calculated (Table 2).

OBSERVATIONS AND DISCUSSION

Of the 252 glomeruli studied in the sections of the kidney removed four years before death, 8 (3 per cent) were so completely hyalinized that little can be said concerning the mechanism of the fibrosis. The remaining 244 glomeruli showed nothing that could be interpreted as intercapillary hyaline thickening except for a single hyaline mass in the periphery of one glomerular lobule (Fig. 1). It is generally agreed that such masses are specific for the histologic picture in the kidney in diabetes mellitus if they are also associated with additional axial manifestations of hyaline thickening. It is noteworthy that this single glomerulus containing the hyaline mass showed no other thickening of the glomerular axis.

This isolated glomerular lesion may have represented the onset of intercapillary glomerulosclerosis. This is unlikely since it would be reasonable to expect that in the kidney obtained at autopsy, in which the fully developed picture of intercapillary glomerulosclerosis was seen, some glomeruli involved by a mild or early process should have been found simulating the isolated lesion discovered in the earlier specimen. As pointed out below, it is striking that none of the glomeruli seen at autopsy showed this picture, wherever discrete hyaline masses were found they were always associated with thickening of other parts of the glomerular axis. Accordingly, we believe that the single lesion described above bears no relation to the intercapillary glomerulosclerosis that developed later. It probably represents the reparative process con-

sequent to a variety of glomerular injuries not related to the diabetic state.

Of the 203 glomeruli studied in the kidney obtained at autopsy, 25 were so completely hyalinized that little can be said concerning the mechanism of the fibrosis. Only 1 glomerulus out of the remaining 178 was devoid of intercapillary thickening. Various degrees of this abnormality from severe to mild were found. Because of confusion in the literature regarding the various stages of this process,⁹ we consider it indispensable to grade the degree of renal involvement according to the extent of the

FIGURE 1 Section of Kidney Removed Four Years before Death. A glomerulus with a single intercapillary hyaline mass (hematoxylin and eosin stain $\times 450$).

process in each glomerulus and the percentage of glomeruli so affected (Table 2) as some authors have attempted.^{6,7} The lesions of severe degree were found in 47.5 per cent of the glomeruli (Fig. 2-4). An additional 40 per cent showed less severe lesions comprising moderately severe lesions in 25 per cent and mild lesions in 15 per cent.

The relatively high percentage of the severe lesions in the kidney removed at autopsy represents an advanced stage in the development of intercapillary glomerulosclerosis and is considered consistent with the diagnosis of diabetes mellitus. Allen¹⁰ has recently stated, "I am altogether convinced of the specificity of the nodular lesion," and

Bell⁷ considers this lesion almost pathognomonic for diabetes. The mild lesions are considered by some authors as the forerunner of the nodular type, but their relation to diabetes has not been established.⁹ The moderately severe lesions are believed

The positive correlation between the severity of the renal lesions of intercapillary glomerulosclerosis and the degree of albuminuria has been emphasized by Henderson et al.⁵ and others.^{7, 9} Our patient showed no albuminuria during the four years prior to nor during the fourteen months following the nephrectomy in April, 1940. In July and August, 1941, during the period of severe sepsis and sulfathiazole treatment, all urine examinations revealed + to ++ tests for albumin (Table 1). In spite of recurrent sepsis and sulfadiazine therapy from September to November, 1941, albuminuria was absent. Repeated urine examinations until December, 1942, showed no albumin. Appearance and disappearance of albuminuria are consistent with an acute inflammatory process that healed. The possibility that the transient albuminuria was due to intercapillary glomerulosclerosis is unlikely because in the latter condition the albuminuria is constant⁷ and continuous once it appears. Thus,

FIGURE 2 Section of Kidney Removed at Autopsy
A glomerulus with intercapillary hyaline thickening and two large discrete hyaline masses (hematoxylin and eosin stain $\times 450$)

to represent an intermediate stage in the development of the severe or nodular lesions.⁸

Other lesions such as afferent arteriolar hyalinization and glomerular capsular thickening and adhesions not generally considered an essential part of the picture of intercapillary glomerulosclerosis were present in the glomeruli of both kidneys. There was some increase in the incidence of these lesions in the four-year interval. Hyalinization of the afferent arterioles as seen in so-called benign nephrosclerosis increased from 7 to 17 per cent. The thickened glomerular capsules increased from 16 to 33 per cent. The incidence of adhesions of the glomerular tuft to the glomerular capsule, considered by many a concomitant of chronic glomerulonephritis, increased from 4 to 9 per cent. Because of the nonspecificity of hyalinized glomeruli their increase from 3 to 12 per cent cannot be considered of much help in evaluating the development of the lesions of intercapillary glomerulosclerosis.

FIGURE 3 Section of Kidney Removed at Autopsy
A glomerulus with intercapillary hyaline thickening and small irregular and large discrete hyaline masses (hematoxylin and eosin stain $\times 450$)

beginning in December, 1942, albuminuria recurred without any antecedent infection and continued in massive amounts until the patient died from renal insufficiency in August, 1944. In view of the large number of severe lesions of intercapillary glomerulo-

sclerosis found in the remaining kidney at autopsy, we believe that the correlation between these lesions and the massive continuous albuminuria is justifiable.

Intercapillary glomerulosclerosis, retinopathy and neuropathy are considered by many as degenerative concomitants of the diabetic state.⁵⁻¹⁰ Henderson et al⁵ called attention to the close relation between advanced diabetic retinopathy and the severe lesions of intercapillary glomerulosclerosis.

In our patient the clinical evidence for degenerative phenomena associated with diabetes developed as follows: diabetes mellitus was first discovered in 1936 and was readily controlled by dietary regulation and moderate or small doses of insulin until 1941, when she was hospitalized for severe sepsis after high ligation of the saphenous veins. From the beginning of the ten-month period of hospitalization insulin was unnecessary until the terminal illness in 1944. Peripheral neuropathy developed in 1942 and improved slightly during the remainder of her life. Impairment of vision, first noted in 1942, progressed gradually until serious reduction of vision associated with advanced diabetic retinopathy was found in 1944.

It is noteworthy that in spite of the excellent control of the diabetic state, neuropathy, retinopathy and massive albuminuria developed six years after the discovery of diabetes mellitus and persisted to the eighth year, when the patient died from renal insufficiency. This observation is similar to those of other authors,¹¹⁻¹² one of whom stated that "the duration of diabetes mellitus rather than the method of treatment is the most important factor in the development of the degenerative changes."¹⁰

At no time, however, did our patient present the nephrotic syndrome, and renal insufficiency supervened only in her terminal illness. In this connection it is noteworthy that intercapillary glomerulosclerosis of as severe degree as was found in this patient is not necessarily associated with the nephrotic syndrome originally observed in the cases described by Kimmelstiel and Wilson.¹ The development of the nephrotic syndrome may be related to the duration of the severe intercapillary lesions before renal insufficiency occurs.

Of fundamental importance is the demonstration that our patient showed no pathological evidence of intercapillary glomerulosclerosis at the time of the nephrectomy although she had been suffering from diabetes and mild hypertension for four years, and yet at some time during the next four years degenerative phenomena in the peripheral nerves and eyes and also massive albuminuria supervened. Clinical evidence of the pathologic renal process did not appear until two years before death, in the sixth year of the diabetes, and at autopsy the fully developed picture of severe intercapillary glomerulosclerosis in the remaining kidney was evident.

On the basis of clinical observation on 43 patients Mann et al¹³ reported that the average duration of life after the appearance of signs of renal disease was six and four-tenth years (range two to twelve years). Our patient's rapid course may have been due to sepsis or the fact that she had only one kidney when the degenerative phenomena associated with diabetes mellitus developed, or to both.

SUMMARY

A single kidney obtained at autopsy from a patient with diabetes mellitus of eight years' duration

FIGURE 4. Section of Kidney Removed at Autopsy. Two glomeruli with intercapillary thickening and multiple small irregular and large discrete hyaline masses (Fematoxylin and eosin stain $\times 300$).

showed severe intercapillary sclerosis in 47.5 per cent of the glomeruli. The other kidney, removed four years earlier for a suspected neoplasm, showed no evidence of intercapillary glomerulosclerosis.

Six years after the onset of diabetes mellitus, neuropathy, retinopathy and massive albuminuria developed and persisted until the eighth year, when the patient died from renal insufficiency. At no time was the nephrotic syndrome present.

The lesions of intercapillary glomerulosclerosis definitely developed during the last four years of life and possibly only during the last two years.

Bell⁷ considers this lesion almost pathognomonic for diabetes. The mild lesions are considered by some authors as the forerunner of the nodular type, but their relation to diabetes has not been established.⁹ The moderately severe lesions are believed

FIGURE 2 Section of Kidney Removed at Autopsy.

beginning in December, 1942, albuminuria recurred without any antecedent infection and continued in massive amounts until the patient died from renal insufficiency in August, 1944. In view of the large number of severe lesions of intercapillary glomerulo-

MATERIALS AND METHODS

Three hundred consecutive urine tests submitted to the laboratory of the Mallory Institute of Pathology of the Boston City Hospital for the diagnosis of possible pregnancy comprise this report. These tests represent all the varieties of diagnostic problems that may be encountered in any general-hospital laboratory, and, so far as possible, all the samples are consecutive. Hence the present report should reflect common clinical experience. As in any general pregnancy diagnostic work, the urine specimens submitted for hormonal assay fell into one of several fairly well defined clinical categories. For the most part these can be stated as possible normal pregnancy, possible ectopic pregnancy, possible fetal death or miscarriage, in which the problem of evaluating the viability of the gestation hinges on the hormone level in the urine, and a pelvic mass in which the differential diagnosis lies between intra-abdominal tumor and pregnancy or both. Almost all the 300 tests fell into one of these four groups. A few tests were performed after surgical removal of hydatidiform moles. Since each of these categories presents a somewhat different laboratory diagnostic problem, it seems advisable to study each group separately. Thus the performance of the frog test can be specifically evaluated in each category, undistorted by the good or bad results obtained in the others.

In each case the validity of the laboratory diagnosis was checked by a clinical follow-up study of the patient, for such time as was required to make certain the clinical status of the patient. In normal pregnancies, a clinical follow-up period of a few months usually sufficed. In the urine samples submitted from patients suspected of miscarrying, the exact status of the pregnancy at the time of performance of the test was frequently very difficult to ascertain. Many such tests were therefore discarded as being insufficiently clearcut from the clinical standpoint for inclusion. When possible, histologic study of curettage or surgical specimens was used to corroborate the clinical diagnosis. In a few cases parallel injections with rats or rabbits were employed as controls for the frog test. Whatever the method, in each test cited in the present series a careful evaluation of the validity of the test was finally achieved.

The technic for performance of the test is substantially identical with that reported in an earlier paper and is therefore described only briefly.⁵ In essence, it consists in the injection of 5 cc of first-morning urine into the dorsal lymph sac of adult male frogs. No preliminary treatment of the urine is required except for occasional crude filtration of grossly turbid specimens. Approximately half an hour after the injection microscopical examination of the cloacal fluid for sperm is begun, the hanging-drop technic being used. The reaction of the

individual animal is followed for approximately two hours unless a positive reaction occurs earlier. As indicated before, to the best of our knowledge, no reaction ever begins after a two-hour interval. In general, positive reactions begin in thirty to forty-five minutes and persist for several hours, and in general they represent "all-or-none" responses. Rarely, an animal reacts with the release of only a few sperm. Our experience indicates that in a positive reaction many sperm may be found in any high-power field. The basis for so-called weakly positive reactions is obscure, but it is clear that they bear no apparent relation to the original titer of hormone injected, probably representing variations in the reactivity of the individual frog. All tests have been performed on adult male frogs run in pairs, the animals being obtained from local collectors. However, since the animals used are captured in the wild state and since estimation of age, to say nothing of sex, is difficult, it would be wise when possible to use 3 animals per test, simply to lower the mathematical probability of encountering all immature or superannuated animals on any given specimen of urine. Although this difficulty in selecting suitable animals may be of some theoretic significance, practically speaking our results indicate that it has not offered any real problem. For similar reasons it is probably good practice to open all "negative test" frogs simply to ascertain by inspection of the gonads that the animals used are male, the external features being insufficiently characteristic for most workers to separate definitely males from females.

RESULTS

The results are presented and discussed under each of four headings cited above.

Possible Pregnancy

As mentioned earlier this category is meant to include patients who present themselves to the physician as possibly pregnant with a history of a missed menstrual period or some disturbance in the regularity of the menstrual cycle. A total of 242 urine tests fall into this group, with the following results: correct positive, 113, correct negative, 117, false positive, 1, and false negative, 11.

With relation to the correct-positive reactions, it is obvious that these tests merely indicate the presence of an apparently uncomplicated early pregnancy. It is well known that at the beginning of pregnancy the titers of gonadotropin are extremely low and only begin to rise to any appreciable level after approximately fifteen days of gestation. Since many urine samples are submitted for analysis after only one or two days of amenorrhea, some even before the first missed period, it did not seem justifiable to call these extremely early negative tests false negative. It was arbitrarily decided, therefore, that fifteen days after the first missed period was

when the degenerative phenomena and massive albuminuria mentioned above were found

THE RELIABILITY OF THE MALE NORTH AMERICAN FROG (*RANA PIPIENS*) IN THE DIAGNOSIS OF PREGNANCY*

S. L. ROBBINS, M.D.,† AND F. PARKER, JR., M.D.‡

BOSTON

WITHIN the past two years many reports summarized by Galli-Mainini¹ have appeared describing a new technic for diagnosis of pregnancy utilizing male amphibia. A great many species of frogs and toads have been described as useful for this procedure, and it is highly probable that many varieties of amphibia have equal value. At the present time two species have received the greatest attention. Galli-Mainini,² working in South America, has used a toad indigenous to that area—the *Bufo arenarum*. His recent report on the results of approximately 1000 tests using this amphibian indicates a high degree of accuracy, approximately 98 per cent, with no false-positive results, the 2 per cent errors being false-negative reactions. In the United States a widely indigenous frog, the common leopard frog known as the *Rana pipiens*, has been used for this work, chiefly by Wiltberger and Miller,^{3, 4} and Robbins and Parker.⁵ To date reports from these North American sources have been of a provisional type, and no extended clinical trial has yet been cited. The advantages of the use of male amphibia are so striking that the technic has created wide interest and possibly considerable use. It therefore seems both necessary and urgent to report results obtained to date with the use of the male frog. Only thus can it be determined whether the test is of sufficient sensitivity and specificity to merit further use.

The practical advantages of this technic are so striking that only a lack of accuracy could block its widespread adoption. In contrast to the five days required for the performance of an Aschheim-Zondek test on immature rats or the two days re-

quired by the female rabbit in the Friedman modification, the male-frog test requires at the most two hours.

The cost of male frogs is only a small fraction of that of rats or rabbits, and, moreover, the amphibia can be kept in small aquaria. From the standpoint of economy and ease in maintenance of a stock of available animals, the frogs are therefore vastly superior to these mammalia.

The only significant problem encountered to date in the use of these amphibia has been alluded to in an earlier report⁶—namely, the toxicity of many urines for them. At the time of the previous writing,⁶ death of the frogs subsequent to their injection with 5 cc of whole urine was a frequent occurrence. For totally obscure reasons, this problem has become much less bothersome at the present time, being no more common with male frogs than with other types of laboratory assay animals. However, it was because of this toxicity of urine that blood serum, containing fewer waste metabolites than urine, was suggested as a method of circumventing the problem.⁶ Accordingly, 5 cc of blood serum was substituted for urine in the performance of the test. Although on purely theoretic grounds serum should contain an adequate source of gonadotropic hormones during pregnancy, and although serum has been successfully substituted for urine in the performance of the Friedman test as well as others, it soon became apparent that serum was quite unsatisfactory for the *Rana pipiens* test. In a fairly large number of patients studied, proved subsequently to be pregnant, serum gave many false-negative results—about 15 to 20 per cent of the total series.⁷ As a consequence, the substitution of serum in the performance of this technic has been dropped, and the present communication concerns itself only with an analysis of the results of the use of urine.

MATERIALS AND METHODS

Three hundred consecutive urine tests submitted to the laboratory of the Mallory Institute of Pathology of the Boston City Hospital for the diagnosis of possible pregnancy comprise this report. These tests represent all the varieties of diagnostic problems that may be encountered in any general-hospital laboratory, and, so far as possible, all the samples are consecutive. Hence the present report should reflect common clinical experience. As in any general pregnancy diagnostic work, the urine specimens submitted for hormonal assay fell into one of several fairly well defined clinical categories. For the most part these can be stated as possible normal pregnancy, possible ectopic pregnancy, possible fetal death or miscarriage, in which the problem of evaluating the viability of the gestation hinges on the hormone level in the urine, and a pelvic mass in which the differential diagnosis lies between intra-abdominal tumor and pregnancy or both. Almost all the 300 tests fell into one of these four groups. A few tests were performed after surgical removal of hydatidiform moles. Since each of these categories presents a somewhat different laboratory diagnostic problem, it seems advisable to study each group separately. Thus the performance of the frog test can be specifically evaluated in each category, undistorted by the good or bad results obtained in the others.

In each case the validity of the laboratory diagnosis was checked by a clinical follow-up study of the patient, for such time as was required to make certain the clinical status of the patient. In normal pregnancies, a clinical follow-up period of a few months usually sufficed. In the urine samples submitted from patients suspected of miscarriage, the exact status of the pregnancy at the time of performance of the test was frequently very difficult to ascertain. Many such tests were therefore discarded as being insufficiently clearcut from the clinical standpoint for inclusion. When possible, histologic study of curettage or surgical specimens was used to corroborate the clinical diagnosis. In a few cases parallel injections with rats or rabbits were employed as controls for the frog test. Whatever the method, in each test cited in the present series a careful evaluation of the validity of the test was finally achieved.

The technic for performance of the test is substantially identical with that reported in an earlier paper and is therefore described only briefly.⁵ In essence, it consists in the injection of 5 cc of first-morning urine into the dorsal lymph sac of adult male frogs. No preliminary treatment of the urine is required except for occasional crude filtration of grossly turbid specimens. Approximately half an hour after the injection microscopical examination of the cloacal fluid for sperm is begun, the hanging-drop technic being used. The reaction of the

individual animal is followed for approximately two hours unless a positive reaction occurs earlier. As indicated before, to the best of our knowledge, no reaction ever begins after a two-hour interval. In general, positive reactions begin in thirty to forty-five minutes and persist for several hours, and in general they represent "all-or-none" responses. Rarely, an animal reacts with the release of only a few sperm. Our experience indicates that in a positive reaction many sperm may be found in any high-power field. The basis for so-called weakly positive reactions is obscure, but it is clear that they bear no apparent relation to the original titer of hormone injected, probably representing variations in the reactivity of the individual frog. All tests have been performed on adult male frogs run in pairs, the animals being obtained from local collectors. However, since the animals used are captured in the wild state and since estimation of age, to say nothing of sex, is difficult, it would be wise when possible to use 3 animals per test, simply to lower the mathematical probability of encountering all immature or superannuated animals on any given specimen of urine. Although this difficulty in selecting suitable animals may be of some theoretic significance, practically speaking our results indicate that it has not offered any real problem. For similar reasons it is probably good practice to open all "negative test" frogs simply to ascertain by inspection of the gonads that the animals used are male, the external features being insufficiently characteristic for most workers to separate definitely males from females.

RESULTS

The results are presented and discussed under each of four headings cited above.

Possible Pregnancy

As mentioned earlier this category is meant to include patients who present themselves to the physician as possibly pregnant with a history of a missed menstrual period or some disturbance in the regularity of the menstrual cycle. A total of 242 urine tests fall into this group, with the following results: correct positive, 113, correct negative, 117, false positive, 1, and false negative 11.

With relation to the correct-positive reactions, it is obvious that these tests merely indicate the presence of an apparently uncomplicated early pregnancy. It is well known that at the beginning of pregnancy the titers of gonadotropin are extremely low and only begin to rise to any appreciable level after approximately fifteen days of gestation. Since many urine samples are submitted for analysis after only one or two days of amenorrhea, some even before the first missed period, it did not seem justifiable to call these extremely early negative tests false negative. It was arbitrarily decided, therefore, that fifteen days after the first missed period was

the earliest date at which a negative test would be accepted as incorrect. Therefore any negative tests before this arbitrary time limit were not considered false negative. Admittedly, fifteen days of amenorrhea comprises a somewhat long wait before a diagnosis is attempted. However, performance of a test before this time involves a calculated risk. When such tests are negative, despite the presence of a viable early pregnancy, considerable clinical confusion invariably follows. If the problem involved in doing tests within the first two weeks of amenorrhea is appreciated, only positive results should be considered as having value. In this same regard 13 tests performed on specimens of urines from patients who were within fifteen days of the first missed period were correctly positive. In fact,

suggesting the likelihood of an abnormal conception or implantation. Tests indicated in Table 1 as numbers 7 to 10 were performed on specimens derived from patients in the third and fourth months of pregnancy. Hormone titers at this time while rapidly falling should nonetheless certainly be detectable. Tests No. 7 and 8 are samples of urine from the same patient, a curious case of undoubted abnormality. The case was thought to represent an intrauterine fetal death with missed abortion, since the size of the uterus never conformed to the calculated duration of the amenorrhea. Two male frog tests were negative, and yet five months later, at a calculated nine months of gestation, a small infant of approximately five months fetal size was born alive and died within two days. Under these

TABLE 1 *False-Negative Reactions*

TEST No	PATIENT	AGE	PERIOD OF AMENORRHEA AT TIME OF PERFORMANCE OF TEST	CLINICAL HISTORY
1	M P C	37	22	Normal pregnancy
2	L H C	34	18 days	Patient pregnant at time of test miscarried 1 mo later
3	C K	—	21 days	Normal pregnancy
4	B B	24	16 days	Normal pregnancy
5	B S B	22	21 days	Normal pregnancy urine specimen received by mail after several days of nonrefrigeration
6	L K	—	16 days	Normal pregnancy
7	E P	28	21 days	Normal pregnancy Patient said to be 9 months pregnant, delivered 5 mo size infant which lived 2 days
8	E P	28	4 mo	Repeat test on above patient
9	M J	26	3 mo	Normal pregnancy urine specimen received by mail
10	M D	—	4 mo	Normal pregnancy
11	T F	—	5 wk	Normal pregnancy

4 specimens were within the first four days after the first missed period. These results are of interest only so far as they indicate that the male frog will react to some early pregnancies, even as the immature rat and rabbit. The 117 correct-negative reactions comprise a mixed group of patients: 10½ with simple amenorrhea, 4 with beginning menopause, and 9 with very early pregnancies that fell within the interval of the first two weeks of amenorrhea mentioned above.

False-negative results merit careful attention and are considered in Table 1.

It can be seen that the first 6 false-negative tests cited were performed on patients within the period of fifteen to twenty-one days of the first missed period. It is entirely possible that these urine samples represent pregnancies with poor production of gonadotropin, since it is well known that individual pregnancies vary greatly in the quantity of hormone excreted. Extreme instances have been cited in which no detectable gonadotropin could be demonstrated throughout a normal pregnancy. In support of the possibility that some of these false-negative tests were due to low-titer urines is the fact that in Case 2 the patient spontaneously miscarried at two and a half months of gestation,

peculiar circumstances, whether the negative frog tests are justifiably considered as falsely negative is a controversial point. Other factors, such as deterioration of the hormone titer of the urine while the specimen is in transit by mail, contributed to the above so-called false-negative results.

The solitary false-positive result encountered in the entire series of 300 tests fell into this group of so-called early normal pregnancies. The patient was a thirty-eight-year-old woman entering the hospital with intense jaundice, apparently of the obstructive type, and associated amenorrhea of two months' duration. The urine specimen submitted for hormonal assay was intensely icteric, giving a positive result on male frogs. Subsequently the patient died, and autopsy demonstrated an obstructing stone in the common duct, bile stasis of the liver with early biliary cirrhosis and a terminal acute hemorrhagic pancreatic necrosis. No evidence of pregnancy could be found. Many speculations might be offered to explain this positive result. Suffice it to say that bile added to normal urine has no effect on the male frogs. Estrogens do not produce spermatism in these animals, and at the present time no good explanation exists for the effect of this type of urine on male frogs. For the

time being therefore, we have avoided icteric urines and thus have not re-encountered this problem

Possible Ectopic Pregnancy

This small group of urines (5 specimens) was derived from women all proved to have ectopic pregnancy by surgical exploration. In most, the presenting clinical features were those of lower abdominal pain and some pelvic mass associated with a disturbance of the regular menses. In the child-bearing age ectopic pregnancy was considered as the probable diagnosis and a urine sample was subsequently submitted for hormonal assay. In 3 cases correct-positive results were obtained, the periods of amenorrhea in the 2 known cases being one month and three months. In another case the urine was submitted before the patient had missed her first period, and the result was negative, as was fully anticipated. Such a result cannot justifiably be termed a false negative. In the last case the patient was three weeks overdue, the frog test was negative, and at laparotomy a tubal pregnancy was found. In the aggregate these results compare favorably with those obtained with the use of any other type of laboratory animal.

Possible Fetal Death

This group of tests is one of the most difficult to evaluate. Patients most of whom are known to be pregnant, begin to have vaginal bleeding, and the question of the viability of the fetus arises. Urine assay remains the only technic presently available for determining viability. Since the exact time of fetal death is seldom, if ever, clear clinically, it is most difficult to ascertain with any surety the exact status of the pregnancy at the time of obtaining the urine sample for assay. Thus, of the many cases of this type tested at this laboratory most had to be discarded. Only cases in which the status of the fetus could be determined fairly certainly at the exact time of performance of the urine test were included in this series. Thus, the total number of acceptable specimens was 23. No incorrect results were encountered. There were 6 correct-positive tests in which it was possible to show that fetal death had not occurred prior to the test and 17 correct-negative tests in which unequivocal evidence, such as passage of placental tissue, indicated the certain death of the fetus. Admittedly, this category has little critical value in the evaluation of a test for pregnancy. The difficulty in judging the clinical course of the pregnancy is so great that when the pregnancy test and the clinical status fail to agree it may well be the clinical impression that is in error. Thus, so-called false results in this group have little real significance since they may simply represent misinterpretation of the clinical status at any given time.

Pelvic Mass

The last group of tests as the heading indicates, is derived from patients having a large pelvic mass representing either a tumor or a pregnancy or both. Seventeen tests comprise the total, and all were received from patients with either uterine leiomyomas or ovarian cysts. No cases of concomitant pregnancy were encountered, and all the tests were correctly negative.

The remainder of the series of 300 tests here reported were made up of tests performed on patients being studied postoperatively after surgical removal of a hydatidiform mole. All these thirteen tests were negative and agreed with the clinical follow-up study of the patients, some for as long as two years.

DISCUSSION

The results already cited for the various categories are summarized in Table 2. It can be seen that of the series of 300 urine tests performed incorrect results were encountered in 13. Thus, the over-all accuracy of this technic may be cited as approximately 96 per cent. One of the incorrect results was falsely positive, the remaining 12 being

TABLE 2 *Results of Pregnancy Test*

Pelvic mass	—	17	—	—
Hydatid moles (follow up study)	—	13	—	—
Totals	122	165	12	1

falsely negative. In terms of false-positive results, the most important consideration, the error was a third of 1 per cent. In addition, it is well to remember that this single false-positive test was encountered in the urine of a patient with intense obstructive jaundice, and although the ultimate basis for this false-positive reaction is still obscure, repetition of the incorrect result can be avoided simply by the rejection of all such icteric urine specimens. Of interest is the fact that an additional sample similar to the one described above was received recently, and although no diagnostic report was submitted, the urine gave a positive test on the male frogs. It was later determined that the patient was not pregnant, implying that the substance present in this icteric urine behaved like the substance present in the earlier, similar specimen. Further study of this problem is now in progress.

This analysis indicates that the male frog test is a procedure of sufficient specificity and sensitivity to merit further use and investigation. Although the frog fails to achieve the accuracy of

the earliest date at which a negative test would be accepted as incorrect. Therefore any negative tests before this arbitrary time limit were not considered false negative. Admittedly, fifteen days of amenorrhea comprises a somewhat long wait before a diagnosis is attempted. However, performance of a test before this time involves a calculated risk. When such tests are negative, despite the presence of a viable early pregnancy, considerable clinical confusion invariably follows. If the problem involved in doing tests within the first two weeks of amenorrhea is appreciated, only positive results should be considered as having value. In this same regard 13 tests performed on specimens of urines from patients who were within fifteen days of the first missed period were correctly positive. In fact,

suggesting the likelihood of an abnormal conception or implantation. Tests indicated in Table 1 as numbers 7 to 10 were performed on specimens derived from patients in the third and fourth months of pregnancy. Hormone titers at this time while rapidly falling should nonetheless certainly be detectable. Tests No 7 and 8 are samples of urine from the same patient, a curious case of undoubted abnormality. The case was thought to represent an intrauterine fetal death with missed abortion, since the size of the uterus never conformed to the calculated duration of the amenorrhea. Two male frog tests were negative, and yet five months later, at a calculated nine months of gestation, a small infant of approximately five months' fetal size was born alive and died within two days. Under these

TABLE 1 *False-Negative Reactions*

4 specimens were within the first four days after the first missed period. These results are of interest only so far as they indicate that the male frog will react to some early pregnancies, even as the immature rat and rabbit. The 117 correct-negative reactions comprise a mixed group of patients: 104 with simple amenorrhea, 4 with beginning menopause, and 9 with very early pregnancies that fell within the interval of the first two weeks of amenorrhea mentioned above.

False-negative results merit careful attention and are considered in Table 1.

It can be seen that the first 6 false-negative tests cited were performed on patients within the period of fifteen to twenty-one days of the first missed period. It is entirely possible that these urine samples represent pregnancies with poor production of gonadotropin, since it is well known that individual pregnancies vary greatly in the quantity of hormone excreted. Extreme instances have been cited in which no detectable gonadotropin could be demonstrated throughout a normal pregnancy. In support of the possibility that some of these false-negative tests were due to low-titer urines is the fact that in Case 2 the patient spontaneously miscarried at two and a half months of gestation,

peculiar circumstances, whether the negative frog tests are justifiably considered as falsely negative is a controversial point. Other factors, such as deterioration of the hormone titer of the urine while the specimen is in transit by mail, contributed to the above so-called false-negative results.

The solitary false-positive result encountered in the entire series of 300 tests fell into this group of so-called early normal pregnancies. The patient was a thirty-eight-year-old woman entering the hospital with intense jaundice, apparently of the obstructive type, and associated amenorrhea of two months' duration. The urine specimen submitted for hormonal assay was intensely icteric, giving a positive result on male frogs. Subsequently the patient died, and autopsy demonstrated an obstructing stone in the common duct, bile stasis of the liver with early biliary cirrhosis and a terminal acute hemorrhagic pancreatic necrosis. No evidence of pregnancy could be found. Many speculations might be offered to explain this positive result. Suffice it to say that bile added to normal urine has no effect on the male frogs. Estrogens do not produce spermatic emission in these animals, and at the present time no good explanation exists for the effect of this type of urine on male frogs. For the

time being, therefore, we have avoided icteric urines and thus have not re-encountered this problem

Possible Ectopic Pregnancy

This small group of urines (5 specimens) was derived from women all proved to have ectopic pregnancy by surgical exploration. In most, the presenting clinical features were those of lower abdominal pain and some pelvic mass associated with a disturbance of the regular menses. In the child-bearing age ectopic pregnancy was considered as the probable diagnosis, and a urine sample was subsequently submitted for hormonal assay. In 3 cases correct-positive results were obtained, the periods of amenorrhea in the 2 known cases being one month and three months. In another case the urine was submitted before the patient had missed her first period, and the result was negative, as was fully anticipated. Such a result cannot justifiably be termed a false negative. In the last case the patient was three weeks overdue, the frog test was negative, and at laparotomy a tubal pregnancy was found. In the aggregate these results compare favorably with those obtained with the use of any other type of laboratory animal.

Possible Fetal Death

This group of tests is one of the most difficult to evaluate. Patients, most of whom are known to be pregnant, begin to have vaginal bleeding, and the question of the viability of the fetus arises. Urine assay remains the only technic presently available for determining viability. Since the exact time of fetal death is seldom, if ever, clear clinically, it is most difficult to ascertain with any surety the exact status of the pregnancy at the time of obtaining the urine sample for assay. Thus, of the many cases of this type tested at this laboratory most had to be discarded. Only cases in which the status of the fetus could be determined fairly certainly at the exact time of performance of the urine test were included in this series. Thus, the total number of acceptable specimens was 23. No incorrect results were encountered. There were 6 correct-positive tests in which it was possible to show that fetal death had not occurred prior to the test and 17 correct-negative tests in which unequivocal evidence, such as passage of placental tissue, indicated the certain death of the fetus. Admittedly, this category has little critical value in the evaluation of a test for pregnancy. The difficulty in judging the clinical course of the pregnancy is so great that when the pregnancy test and the clinical status fail to agree it may well be the clinical impression that is in error. Thus, so-called false results in this group have little real significance since they may simply represent misinterpretation of the clinical status at any given time.

Pelvic Mass

The last group of tests, as the heading indicates, is derived from patients having a large pelvic mass representing either a tumor or a pregnancy or both. Seventeen tests comprise the total, and all were received from patients with either uterine leiomyomas or ovarian cysts. No cases of concomitant pregnancy were encountered, and all the tests were correctly negative.

The remainder of the series of 300 tests here reported were made up of tests performed on patients being studied postoperatively after surgical removal of a hydatidiform mole. All these thirteen tests were negative and agreed with the clinical follow-up study of the patients, some for as long as two years.

DISCUSSION

The results already cited for the various categories are summarized in Table 2. It can be seen that of the series of 300 urine tests performed incorrect results were encountered in 13. Thus, the over-all accuracy of this technic may be cited as approximately 96 per cent. One of the incorrect results was falsely positive, the remaining 12 being

TABLE 2 *Results of Pregnancy Test*

ACTUAL DIAGNOSIS	CORRECT-POSITIVE TESTS	CORRECT-NEGATIVE TESTS	FALSE-NEGATIVE TESTS	FALSE-POSITIVE TESTS

falsely negative. In terms of false-positive results, the most important consideration, the error was a third of 1 per cent. In addition, it is well to remember that this single false-positive test was encountered in the urine of a patient with intense obstructive jaundice, and although the ultimate basis for this false-positive reaction is still obscure, repetition of the incorrect result can be avoided simply by the rejection of all such icteric urine specimens. Of interest is the fact that an additional sample similar to the one described above was received recently, and although no diagnostic report was submitted, the urine gave a positive test on the male frogs. It was later determined that the patient was not pregnant, implying that the substance present in this icteric urine behaved like the substance present in the earlier, similar specimen. Further study of this problem is now in progress.

This analysis indicates that the male frog test is a procedure of sufficient specificity and sensitivity to merit further use and investigation. Although the frog fails to achieve the accuracy of

the immature rat in the Aschheim-Zondek test, the many other advantages of the use of the frog seem to outweigh this small difference in sensitivity. In competent hands the Aschheim-Zondek test employing immature rats achieves an accuracy of close to 99 per cent, compared with the 96 per cent of the frog test. This difference in sensitivity is of some theoretic interest since repeated parallel assays of urine samples on rats and frogs indicate a complete identity of sensitivity to gonadotropins for the two types of animals. The theoretic basis, therefore, for this difference in accuracy between the rat and frog is totally obscure.

The results here reported are intended to serve as a progress report and possible stimulus to further modification and investigation of this technic. In this regard, we are privileged to include several suggestions, as yet unreported, that may well enhance the accuracy of this test to a point where it will compare favorably with all other technics.

Goodof,⁸ having available an abundant source of vigorous frogs, submits all newly received animals to a screening injection of a minimal reacting dose of chorionic gonadotropic hormone. Frogs failing to respond to this dosage level are discarded. By this means females, poorly developed males and subreactive animals are eliminated, and only known reactors are then used for diagnostic work. More recently, Elrich, Albright and Brenner,⁹ working with the male *Rana pipiens*, encountered a high percentage of toxic urines. To avoid this problem, dialysis of whole urine against slowly running cold tap water for an hour was employed, following similar technics by Heller et al.¹⁰ After this treatment it was found that all urine specimens were completely nontoxic, and therefore 10 cc of urine was employed as the routine injection dose, doubling the size of the previous dose. Heller and Chandler¹⁰ have shown that no hormone titer is lost in this dialysis treatment, and, therefore, with the use of 10 cc of urine the sensitivity of the frog test has been appreciably increased. To date no false results have been encountered by these workers. The increased dosage that dialysis permits may well bring the accuracy of the frog test up to the level of the Aschheim-Zondek procedure. Another method of handling toxic urines has been used recently.¹¹ It comprises the precipitation of the hormone by the use of a mixture of ether and 95 per cent alcohol. The precipitate obtained is dissolved in saline solution and injected. This method is said to permit the use of larger volumes of urine and thus to enhance the sensitivity of the test. Moreover,

the simple use of 3 frogs for each urine assay may well enhance the accuracy of this technic by mathematically lowering the probability of encountering all nonreactive animals. What effect on the accuracy of the male-frog test these various modifications may have is as yet not known, however, they bear promise for the future.

SUMMARY

Three hundred routine, essentially consecutive urine specimens have been submitted to pregnancy hormonal assay utilizing the male-frog (*Rana pipiens*) test.

An over-all accuracy of approximately 96 per cent has been achieved. A single false-positive test, now believed to be readily avoidable, and 12 false-negative reactions were encountered.

The analysis of the results indicates that most of the false-negative reactions were encountered in cases of normal pregnancy within the first month of amenorrhea. Yet several positive tests were obtained in other cases within the first four days of amenorrhea, indicating that the problem is not one alone of insensitivity of the frog to chorionic gonadotropin, but of varying hormone levels in individual pregnancies.

The results obtained appear to justify the continued use and study of this diagnostic technic. Several possible modifications having considerable promise are mentioned.

Since this paper was submitted for publication the technic for the performance of the test has been modified. Twenty cubic centimeters of urine per frog is precipitated with 4 vol of 95 per cent alcohol. The sediment obtained by vacuum filtration is dissolved in saline solution and injected. The results appear to be somewhat superior to those obtained with whole urine.

We are indebted to Mrs. Phyllis B. Marshall and Miss Gloria E. Mannix for their technical assistance.

FATAL PANCYTOPEMIA FOLLOWING THE USE OF "MESANTOIN"*

Report of a Case

RUSSELL W. WELLER, M.D.,† AND JAMES METCALFE, M.D.‡

NEWPORT, RHODE ISLAND

"MESANTOIN" (3-methyl-5, 5-ethylphenyl-hydantoin), a close chemical relative of dilantin has been used as an anticonvulsant in the treatment of grand-mal seizures since 1945. In 1946 Harrison, Johnson and Ayer¹ reported a case of fatal aplastic anemia following the use of "mesantoin" and tridione. Since that time several cases of pancytopenia following the use of "mesantoin" have been reported.^{2, 3} The following case of fatal pancytopenia occurring after the use of "mesantoin" is presented to stimulate further investigation of the properties of this drug.

CASE REPORT

L. V. D., a 31-year-old veteran of World War II entered the United States Naval Hospital, Newport, Rhode Island, on January 7, 1949, complaining of bleeding from the right nostril of 2 days' duration. The nostril had been packed by his physician, but bleeding continued. He was admitted to the ear, nose and throat service, where local treatment with silver nitrate, fibrin foam and two blood transfusions of 500 cc each failed to stop the bleeding. On January 12 he was transferred to the medical service, where it was learned that he had been taking "mesantoin" and phenobarbital for 6 months prior to entry because of "epileptic attacks," which allegedly followed a skull fracture in 1944. He had continued to take "mesantoin" in a dosage of 0.1 gm daily until January 6, and had taken none since.

There was no family history of bleeding abnormality, and he had no past history of joint pains, visceral pain or hemorrhagic tendencies. He had noted no hematuria, hematemesis or melena.

Physical examination on January 12 revealed a pale thin man in no acute distress. The right nostril contained a large, dark clot from beneath which oozed bright-red blood. There was a linear depression of the skull in the left frontal area. There were numerous discrete petechial hemorrhages in the skin over the entire body varying from pin-point size to 5 mm in diameter. The mucous membranes were pale, and the uvula was swollen and dark. There was no palpable lymphadenopathy, the lungs were clear, and the heart was normal to physical examination except for the tachycardia. The liver edge was just palpable beneath the right costal margin and the spleen could not be felt. Neurologic examination revealed no abnormalities.

The temperature was 101.2°F by mouth, the pulse 120, and the respirations 20. The blood pressure was 125/80.

Examination of the blood disclosed a red-cell count of 3,350,000, with a hemoglobin of 9.8 gm per 100 cc. The urine was normal, and smears for malaria were negative. The bleeding time was 2 minutes, the coagulation time 2½ minutes (Lee and White method), and the clot retraction was very poor. On the 5th hospital day the red-cell count was 2,130,000, with 6.23 gm of hemoglobin, and the white-cell count 1850, with 86 per cent lymphocytes and 14 per cent neutrophils. The color index was 0.98, and a smear of the peripheral blood revealed anisocytosis, poikilocytosis and toxic granulation of the neutrophils. The prothrombin time (Quick quantitative method) was 15 seconds (control, 13 seconds), and the blood urea nitrogen 17.8 mg per 100 cc of whole blood. Sternal-marrow aspiration smears revealed an aplastic marrow with an average of 1 normoblast in six oil immersion fields. The icteric index was 10, the cephalin-flocculation reaction + + + +, and the platelet count 36,000.

†Pathologist, United States Naval Hospital formerly resident in pathology Jefferson Medical College Hospital Philadelphia.

‡Member Medical Staff United States Naval Hospital formerly medical house officer Peter Bent Brigham Hospital Boston.

In spite of the measures outlined below the pancytopenia progressed, with a red-cell count of 1,880,000 and a white-cell count of 1400 on the 9th hospital day. On the 14th day (the day of death) the red-cell count was 1,910,000, the white-cell count 1000, and the platelet count 24,000.

The patient was treated with daily transfusions of whole blood, intramuscular injections of penicillin, liver extract and "pentnucleotide," intravenous administration of vitamin K, oral administration of vitamin C, folic acid and yellow bone marrow. After each blood transfusion his temperature rose, but there were no other manifestations of a transfusion reaction. A tourniquet test on January 13 yielded complete ecchymosis in the test area. This test was repeated on January 19, when only 10 pin-point petechiae were obtained in the test area. This change in response coincided with the clinical impression of improvement, although the laboratory findings gave an entirely different view, and his temperature remained elevated, spiking to 105°F after each transfusion. On January 20 a chest x-ray film showed mottled pneumonic infiltration in the left mid-lung field. X-ray films of the long bones were normal. Penicillin was continued.

On the morning of January 22 the patient was found unconscious in bed. Respirations were labored, and the cardiac rate was 96, with distant heart sounds. Moist rales were audible scattered throughout both lung fields. He was placed in an oxygen tent, but respirations ceased shortly thereafter.

Post-mortem examination revealed petechial hemorrhages in the skin of the extremities, chest and abdomen. There was a large amount of dried blood in the nares and pharynx. Diffuse subpericardial and subpleural hemorrhages were present, as well as subserosal hemorrhages of the entire gastrointestinal tract. There were subcapsular hemorrhages of both kidneys, as well as submucosal hemorrhages of the pelvis and ureters. Numerous large, poorly defined hemorrhagic areas were seen in both lungs, along with a moderate amount of pulmonary edema and carnification of the left lower lobe with pleural thickening. Examination of the brain showed several large subdural hemorrhages and large areas of cortical necrosis on the ventral aspects of the frontal and temporal lobes extending into the white matter. Many recent hemorrhages were present in the frontal, parietal and temporal cortex. The bone marrow was yellowish brown.

Microscopic examination disclosed terminal subendocardial and subepicardial hemorrhages, with early necrosis of the adjacent myocardium. There was moderate pulmonary edema, organizing lobar pneumonia in sections from the left lower lobe and recent hemorrhage into the alveoli in many sections. Recent and older partially absorbed hemorrhages were present in the cerebral cortex and white matter, and advanced cortical necrosis was observed. The sternal-marrow blocks showed marked aplasia with increased fat, reticulum cells, a rare erythroblast and a rare myelocyte. No megakaryocytes were seen.

SUMMARY AND CONCLUSION

A case of fatal pancytopenia following the use of "mesantoin" and phenobarbital is presented. Autopsy revealed multiple visceral and cutaneous hemorrhages, an organizing lobar pneumonia and an aplastic bone marrow.

Accumulating evidence suggests that further investigation of the possible toxic properties of "mesantoin" is advisable.

the immature rat in the Aschheim-Zondek test, the many other advantages of the use of the frog seem to outweigh this small difference in sensitivity. In competent hands the Aschheim-Zondek test employing immature rats achieves an accuracy of close to 99 per cent, compared with the 96 per cent of the frog test. This difference in sensitivity is of some theoretic interest since repeated parallel assays of urine samples on rats and frogs indicate a complete identity of sensitivity to gonadotropins for the two types of animals. The theoretic basis, therefore, for this difference in accuracy between the rat and frog is totally obscure.

The results here reported are intended to serve as a progress report and possible stimulus to further modification and investigation of this technic. In this regard, we are privileged to include several suggestions, as yet unreported, that may well enhance the accuracy of this test to a point where it will compare favorably with all other technics.

Goodof,⁸ having available an abundant source of vigorous frogs, submits all newly received animals to a screening injection of a minimal reacting dose of chorionic gonadotropic hormone. Frogs failing to respond to this dosage level are discarded. By this means females, poorly developed males and subreactive animals are eliminated, and only known reactors are then used for diagnostic work. More recently, Elrich, Albright and Brenner,⁹ working with the male *Rana pipiens*, encountered a high percentage of toxic urines. To avoid this problem, dialysis of whole urine against slowly running cold tap water for an hour was employed, following similar technics by Heller et al.¹⁰ After this treatment it was found that all urine specimens were completely nontoxic, and therefore 10 cc of urine was employed as the routine injection dose, doubling the size of the previous dose. Heller and Chandler¹⁰ have shown that no hormone titer is lost in this dialysis treatment, and, therefore, with the use of 10 cc of urine the sensitivity of the frog test has been appreciably increased. To date no false results have been encountered by these workers. The increased dosage that dialysis permits may well bring the accuracy of the frog test up to the level of the Aschheim-Zondek procedure. Another method of handling toxic urines has been used recently.¹¹ It comprises the precipitation of the hormone by the use of a mixture of ether and 95 per cent alcohol. The precipitate obtained is dissolved in saline solution and injected. This method is said to permit the use of larger volumes of urine and thus to enhance the sensitivity of the test. Moreover,

the simple use of 3 frogs for each urine assay may well enhance the accuracy of this technic by mathematically lowering the probability of encountering all nonreactive animals. What effect on the accuracy of the male-frog test these various modifications may have is as yet not known, however, they bear promise for the future.

SUMMARY

Three hundred routine, essentially consecutive urine specimens have been submitted to pregnancy hormonal assay utilizing the male-frog (*Rana pipiens*) test.

An over-all accuracy of approximately 96 per cent has been achieved. A single false-positive test, now believed to be readily avoidable, and 12 false-negative reactions were encountered.

The analysis of the results indicates that most of the false-negative reactions were encountered in cases of normal pregnancy within the first month of amenorrhea. Yet several positive tests were obtained in other cases within the first four days of amenorrhea, indicating that the problem is not one alone of insensitivity of the frog to chorionic gonadotropin, but of varying hormone levels in individual pregnancies.

The results obtained appear to justify the continued use and study of this diagnostic technic. Several possible modifications having considerable promise are mentioned.

Since this paper was submitted for publication the technic for the performance of the test has been modified. Twenty cubic centimeters of urine per frog is precipitated with 4 vol of 95 per cent alcohol. The sediment obtained by vacuum filtration is dissolved in saline solution and injected. The results appear to be somewhat superior to those obtained with whole urine.

We are indebted to Mrs. Phyllis B. Marshall and Miss Gloria E. Mannix for their technical assistance.

of the United States) any increase in diphtheria will be likely to affect adults relatively more than children. For effective immunization in children should leave only a small proportion unprotected—perhaps 2 to 10 per cent—whereas the figures of Schick²⁵ and others indicate that at least 15 to 20 per cent of adults are Schick positive and therefore presumably susceptible to diphtheria. Moreover the early observations of Park²⁶ variously confirmed during the last twenty years have shown that these figures are representative only for adults from urban or otherwise congested areas far higher Schick-positive rates being found among many adult groups. Twenty-five years ago White²⁷ in Massachusetts, found 75.5 per cent of country school-teacher's, 77 per cent of Smith College students and 35 per cent of all adults surveyed to be Schick positive.²⁷ A similar observation²⁸ made by Crooks in 1925²⁸ is true, that some recent surveys have found no more than 24 to 30 per cent Schick-positive reactors among American military personnel²⁹⁻³² and even lower rates have been noted elsewhere³³⁻³⁵. But numerous other reports disclose much higher Schick-positive rates among Americans—for example 29 to 45 per cent in medical students³⁶ 49 per cent and 70 per cent in student nurses³⁷ 35 40 per cent in prison inmates and 51 per cent to 82 per cent in parents or teachers³⁹⁻⁴⁰ 34 per cent in 18,000 Navy recruits⁴¹ and 42 per cent in a smaller Navy group⁴² and 44 per cent in 2983 Army personnel⁴³. In other countries similar figures have appeared from 42 to 87 per cent positive reactors among various adult groups in Canada⁴⁴, 46 to 60 per cent among Australian medical and nursing students⁴⁵, 51 per cent among English mothers⁴⁶, and 67 per cent among Norwegian mothers⁵⁰. Finally diphtheria may occur under some conditions in persons who have immunity equivalent to the level of a negative Schick test, Ipsen⁵¹ has reported a series of cases observed during the wartime epidemic in Denmark, in which diphtheria occurred despite an immunity level far above the accepted minimum supposedly adequate for protection. Thus, it is necessary not only to revise established concepts regarding the general level of Schick positiveness in adults but also to re-emphasize the fact that a negative Schick test is not an infallible indication of immunity.

Efficacy of Immunization

One may ask at this point, What evidence is there that diphtheria immunization is actually effective? What have been the actual proved results following its use? Certain of the answers to this question, already summarized,¹¹ indicated that adequate immunization against diphtheria has given as much as 85 to 95 per cent protection. Several recent reports from widely scattered areas have supported these figures⁵²⁻⁵⁵. However a few studies have not been so optimistic, showing only

about a 50 per cent protection rate⁵⁶⁻⁵⁹. Practically all reports note that cases in the immunized, where they do occur are relatively mild with few or no deaths. In a Swedish series for example, the death rate was 1.6 per cent (1 in 61) in inoculated compared to 11.7 per cent (24 in 267) among the uninoculated patients⁵⁵. This is strikingly confirmed by Ipsen,⁵¹ who observed 8.7 per cent deaths among 287 unvaccinated patients as against no deaths among 138 partially or completely vaccinated patients. Poulain²¹ likewise reported 30 deaths in 490 unvaccinated and no deaths in 90 vaccinated patients.

It has been noted previously¹¹ that some failures to achieve protection can be ascribed to a lack of understanding of how to use diphtheria toxoid—for example, the use of two doses of fluid toxoid or one dose of alum toxoid or the administration of any kind of toxoid at one-week intervals. In other instances failure may correctly be attributed to the use of toxoids of insufficient potency. Such instances have been detected by careful observers in England⁶⁰ and Denmark.⁶¹ One wonders whether such a factor played a part in the severe outbreak reported by Fanning⁶² in an English girls' school. Fifteen cases of diphtheria occurred among 299 previously immunized students, whereas 3 occurred among 23 unimmunized pupils. Although 96 per cent of the pupils had been immunized, only 69 per cent were Schick negative. However, several of the cases were in children who had just previously shown a negative Schick test.

In any attempt to evaluate the efficiency of diphtheria immunization, the rate at which immunity wanes must also be considered. It was previously noted¹¹ that anywhere from 3 to 20 per cent reversion to the Schick-positive state has been seen at the end of a year, these studies and others indicate that over a period of four or five years anywhere from 12 to 35 per cent relapses from immunity to susceptibility may be expected⁶³⁻⁶⁵.

In summary, then it appears that from as little as 50 per cent to over 90 per cent protection may be expected from adequate diphtheria immunization, and that in any case the complication and mortality rate in immunized persons will be very low. However, it is unfortunate that few, if any, truly controlled studies on the results of diphtheria immunization have been carried out, so that the efficacy of this procedure cannot be assessed as precisely as for example, that of influenza and pertussis immunization. To be sure, the incidence and severity of diphtheria in many immunized groups have been compared with rates in unimmunized subjects. However, there is little evidence in most such reports that the controls were of comparable economic status, hygienic habits, family size and so forth. Consequently, the claims for diphtheria immunization have been vulnerable to the attacks of the skeptics, among the most ingenious, persistent and

MEDICAL PROGRESS

ACTIVE IMMUNIZATION

GEOFFREY EDSALL, M D *

BOSTON

DURING the past three years there have been many general and special contributions to the subject of active immunization. The principles and practices of pediatric immunization have been discussed in some detail by Miller,¹ who has long combined both practice and research in this field. The latest revision of the American Academy of Pediatrics *Handbook*² takes note of most of the recent revisions in immunization practices and provides, as always, many thought-provoking statements and opinions. Along a different train of thought, Parish³ has presented a stimulating discussion of the present knowledge regarding both principles and practices of prophylactic inoculation, together with a consideration of probable future trends. Top,⁴ as one of several participants in a symposium on immunization procedures,^{4,5} has denoted the criteria that are helpful in assessing the value of an immunizing agent: safety, effectiveness, usefulness and ease of administration. His brief paper illustrates these principles, and considers their significance for both the health officer and the physician in private practice. A further item of usefulness for the practitioner is a pamphlet⁶ recently issued by the United States Public Health Service, summarizing recommended immunization procedures prior to foreign travel.

Most of the problems underlying the principles of immunization remain little advanced as compared to the situation two or three years ago, in some fields, however, new information of significance has appeared. Freund,¹⁰ in a scholarly review of certain aspects of this field, gives particular consideration to the cells responsible for antibody formation, and to the use of adjuvants for enhancement of the immunizing effect of an antigen. Several other lines of research are now being actively pursued by numerous investigators, and may lead within the next few years to significant advances in the understanding of the basic mechanisms that underlie immune phenomena. Meanwhile, it is of value to consider the advances of a somewhat more empirical nature that have taken place in the control by immunization of certain diseases of importance in the northeastern United States: diphtheria, influenza, pertussis, pneumonia, rabies, smallpox, tetanus, tuberculosis and typhoid fever. A previous review¹¹ considered all these diseases except pneumonia and tuberculosis, and also included scarlet fever. Little new information has appeared

regarding immunization against the latter disease, except for a few studies using precipitated antigens,^{12,13} which show promise but require more extensive trial. The present review has of necessity included further consideration of many problems taken up in the 1946 review, space forbids the recapitulation of many developments that were previously considered, and reference is made to the earlier publication for such material when it relates to current findings.

DIPHTHERIA

Recent Trends

Increase in adults. The wave of diphtheria that swept over most of Europe during the recent war has been well summarized by Stowman.¹⁴ The possible effects of this epidemic on diphtheria trends in the United States have been considered in detail by several writers.^{15,17} Whether many new and virulent strains were introduced into this country from Europe, or whether the increase of cases in recent years in the United States was due primarily to domestic factors, as Anderson believes,¹⁶ there is no doubt that marked increases in both the incidence and the severity of diphtheria have been noted in various sections of this country. The rise began to be noticed about 1940, passing its maximum at different times in different localities. Nowhere in the United States were these increases at all comparable with the twentyfold increases observed during the height of the Norwegian and Dutch epidemics. Nevertheless, the fact that a threefold or fourfold increase should occur in a community such as Massachusetts, where extensive immunization programs have been carried out for many years, has called for a re-examination of the factors that determine susceptibility or resistance to diphtheria in the individual as well as in the herd.

One of the outstanding trends in the recent pandemic of diphtheria has been the marked increase in the percentage — and indeed often in the actual numbers — of adult cases. This has been noted in Massachusetts and has been reported from many widely separated areas — such as Minnesota,¹⁸ California,¹⁹ Utah,²⁰ France,²¹ Italy,²² Denmark²³ and Germany²⁴ — and in fact has been characteristic of the entire diphtheria picture in Europe.¹⁴ This shift appears to have been due to two factors. The first is the obvious fact that, where immunization among children has been extensively carried out (as in Denmark, parts of France and many areas

*Director, Division of Biologic Laboratories, Massachusetts Department of Public Health; assistant professor of public health bacteriology, Harvard School of Public Health.

achieve much purification, or to the unusually large amount of toxoid protein that they injected Holt,⁸² ⁸³ of the Wright-Fleming Institute in London, has described a method of preparing a purified aluminum-phosphate-adsorbed toxoid of constant composition, which is relatively free from impurities and highly antigenic Bousfield⁸⁴ ⁸⁵ has reported very satisfactory results from its clinical use Using a different approach Ross⁸⁶ has eliminated a large proportion of the nonbacillary toxoid protein by precipitation with protamine Pillemer,⁸⁷ applying alcohol fractionation in the cold, has obtained a toxoid that is over 90 per cent pure Levine et al⁸⁸ have prepared toxoid of similar purity by ammonium sulfate fractionation All these preparations have proved to be antigenic, and well tolerated in children,⁸⁴ ⁸⁶ ⁸⁹ but such meager data as are available regarding their reactivity in adults indicate that reactions have not been entirely eliminated The recent findings of Pappenheimer and Lawrence⁹⁰⁻⁹² may explain much of the difficulty that has been experienced in this respect Using very highly purified reagents, they demonstrated, in careful quantitative animal studies, that toxoid protein and the other bacillary protein or proteins present in crude toxoid are both antigenic, but are immunologically distinct⁹⁰ They showed that human subjects may be separately sensitive to either toxoid or bacterial protein, or to both, and that this sensitivity may be elicited by extremely small quantities of either substance⁹¹ In general, their subjects who had low antitoxin titers were relatively insensitive to the toxoid protein, whereas exquisite sensitivity to this fraction was rather common among immune subjects Sensitivity to bacterial protein was not closely correlated with serum antitoxin levels, although it was in general more marked in immune subjects Finally, Pappenheimer and Lawrence⁹² have demonstrated that immunity can be produced without discomfort by employing normal doses of purified toxoid in hyposensitive subjects, and reduced doses in hypersensitive subjects This clearcut demonstration that acute sensitivity can exist to toxoid protein may require extensive revision of present concepts of diphtheria immunization, particularly in adults Whatever the final answer may be, it is probable that the use of purified toxoid will become essential, and it is also likely that some sort of control or sensitivity test will still be required in adults before even a purified toxoid can be administered with impunity

Neonatal Immunization

It has long been recognized that the passive transfer of maternal immunity to the newborn infant interfered with neonatal immunization up to the time that such immunity is lost, toward the end of the first half year of life Cooke⁹³ has recently confirmed this by administration of combined diph-

theria-tetanus toxoid to 284 infants, demonstrating a good response to diphtheria toxoid in infants lacking maternally transferred antibodies to diphtheria, a relatively poor response in young infants inheriting passive immunity, and a uniformly good response to tetanus toxoid regardless of age, since there is no inherited immunity against tetanus toxoid These results indicate that too much dependence should not be placed on neonatal immunization of infants against diphtheria However, the use of an antigen potentiated by admixture with adjuvants or combined with other antigens, such as pertussis bacilli, may overcome the handicap inherent in neonatal antidiphtheric immunization Bell⁷⁴ found that 201 infants under six months, who received alum-precipitated toxoid combined with pertussis vaccine, showed essentially the same Schick-negative rate a year later, as was found in 236 older infants given alum-precipitated toxoid alone, and di Sant' Agnese⁹⁴ has observed that the booster response in both age groups is equally good one year after primary immunization

INFLUENZA

Effectiveness of Immunization

Several comprehensive reviews on influenza⁹⁵ and in particular on vaccination against influenza⁹⁶ ⁹⁷ have recently summarized the principal developments of the past few years in the control of this disease As noted in previous reviews,¹¹ ⁹⁵ the large-scale vaccination studies of 1943-1944 in Army personnel showed an influenza attack rate of 2.22 per cent in the vaccinated as against 7.11 per cent in the controls A similar outbreak in an institution,⁹⁸ analyzed in a subsequent report,⁹⁹ showed attack rates of 1.9 per cent in the immunized and 12.4 per cent in the unimmunized — roughly a 6.1 protection rate The next major outbreak, a Type B epidemic in 1945-1946, was studied on two college campuses in this country, where vaccinated Army personnel and unvaccinated Navy personnel were concurrently exposed The protection rates observed in the two studies were 9.1¹⁰⁰ and 24.1¹⁰¹ Simultaneously, a Type B outbreak in England gave opportunity for observing the effects of vaccine in that country, protection rates ranging from 2.1 to 5.1 in different groups were observed¹⁰² On the basis of such observations as these, there appeared to be many valid indications for use of influenza vaccine, even though the apparently short duration of the immunity obtained and the slight but definite danger of reactions were fully recognized¹⁰³ Vaccination was recommended for use in persons with histories of severe influenza, in groups where absenteeism would create significant problems, in crowded colleges and technical schools, and so forth¹⁰³ Some clinicians emphasized the value of immunization for "the very large group of infants and children from several months of age

iconoclastic of whom is Rendu⁶⁶ in Lyon, France. According to Rendu, for example, although the immunization of school children in Geneva in the 1930's was followed by a decrease in diphtheria, there was also a comparable decrease in uninoculated areas, and the recrudescence of diphtheria in Geneva in 1941-1944 was as marked as it was in Neuchâtel, where no immunization program had been carried out. In another article, Rendu⁶⁷ undertakes to refute a series of French reports on the striking effect of toxoid in aborting diphtheria outbreaks in civilian and military personnel. In a recent paper he⁶⁸ dissects some of the data regarding diphtheria immunization in the French Army, particularly with reference to an extensive program for immunizing Schick-positive soldiers, which was claimed by Dopter⁶⁹ to have led to an eightfold reduction in the incidence of the disease among those immunized. These results were based on the premise that all soldiers developing diphtheria prior to completion of immunization should be classed as "unimmunized", as would be expected, a large proportion of cases occurred in this group, since they were invariably new recruits. Rendu challenges this premise and shows that, if all such cases are classed as "immunized," there is no difference in the diphtheria incidence between "immunized" and "unimmunized" troops. Obviously, one cannot accept either Dopter's assumption (that Schick-positive, inoculated troops can be compared with Schick-negative, uninoculated troops) or the extraordinary concept of Rendu that, if a man is scheduled to be injected, he shall be classed as "immunized." Such fallacies weaken Rendu's strongest argument, which is that many items of "evidence" for the efficacy of toxoid are actually inconclusive. Nevertheless, his widespread statements that diphtheria toxoid is not only useless but also perhaps harmful have led in some quarters to a reluctance in accepting immunization. Poulain,²¹ also of Lyon, analyzed the actual results of immunization in that city, and showed that, in each age group, the diphtheria rate in the immunized was about one tenth that in the uninoculated, and furthermore, that no deaths occurred in the immunized persons during the four years of an active immunization program. Furthermore, he presents evidence that, in the last fifteen months of this program alone, 22 deaths in unimmunized children might have been prevented, if about 15 per cent of the population had not ignored or evaded the city's immunization program, in part because of misinformation as indicated above.

Methods of Increasing the Effectiveness of Immunization

Three important approaches may be considered: addition of an adjuvant, increasing the dose, and giving more frequent or more numerous doses. It is well established, for example, that the addition of numerous substances (of which alum is merely

the best known example) will increase the effectiveness of a given quantity of toxoid. Recent laboratory and clinical observations⁷⁰⁻⁷⁴ give strong evidence that a similar effect is achieved by a mixture of toxoid with bacterial suspensions such as pertussis vaccine. Such measures may be of great value in establishing an adequate primary immunity. There is a growing recognition, however, as noted above, that primary immunity will wane sooner or later, and hence that it is necessary to administer "repeat" or "booster" doses at suitable intervals — as when a child first enters school. Numerous studies confirming the efficacy of such a procedure have previously been assembled,¹¹ but the optimum dose for this purpose has yet to be determined. Wishart et al.⁷⁵ gave various quantities of toxin or toxoid to eleven groups totaling 378 persons. They found that 4 flocculating (Lf) units (about 0.1 cc of the usual toxoid) produced an antibody response in over 95 per cent of previously immunized subjects.

Reactions. However, even a 2-Lf dose caused local or general reactions in at least 15 per cent of adults.⁷⁶ In the United States Army, a comparable program elicited marked reactions in 9 to 10 per cent of the subjects injected.⁴³ In another United States Army group the incidence of reaction was apparently reduced by immunization of only the Schick-positive reactors, with graded doses of toxoid.³ However, this is not always practical, and the incidence of reactions found in this study was much lower than that observed in other series. Boyd⁷⁶ attempted to screen a group of 131 British soldiers by testing with Schick toxin and diluted toxoid. The 98 subjects who were not sensitive to the diluted toxoid received 0.2 cc of undiluted alum-precipitated toxoid, almost 40 per cent had severe local or general reactions. A similar experience is reported by Vollum and Wilson⁷⁷ in immunization of nurses. Thus, until a more suitable method for immunization of adults is developed, mass immunization of such groups will continue to present a problem. Another approach to elimination of reactions is to adopt a different route of administration. Masucci, Gold and de Falco⁷⁸ have tried Bousfield's⁷⁹ device, administering toxoid in the form of lozenges placed under the tongue. They observed no untoward reactions, and a good antibody response in previously immunized subjects, but no response in persons who had not previously received immunization, thus they confirmed Bousfield's original observations.

Most recent studies, however, have been directed toward the elimination of the reaction-producing substances in toxoid, which have generally been thought to be the bacterial proteins present in the crude preparation. Peshkin and Rapaport⁸⁰ employed a partially purified toxoid prepared by a calcium phosphate adsorption and elution method.⁸¹ It is difficult to judge whether the severe reactions induced by their product were due to a failure to

Various adjuvants have been employed in efforts to potentiate the effect of a given quantity of influenza virus vaccine. The use of protamine has been suggested¹³⁵ and tried with but indifferent success.¹³² Alum adsorption did not produce a gain.¹³⁹⁻¹⁴⁰ Results of procedures employing calcium phosphate as an adsorbent¹⁴¹ have been inconsistent¹³⁵ but on the whole promising.¹⁴² The most striking effects have been observed after the use of water-in-oil emulsions after the method of Freund.¹⁴³ Influenza virus emulsions of this type have proved to be highly antigenic both in animals¹⁴⁴ and in man.¹³² The relatively high incidence of abscess formation induced by this method, however, is a drawback that has not at present been overcome.

Other Immunization Routes

Intracutaneous vaccination with one or two doses of 0.1 cc of influenza vaccine has been tried, with results superior to those obtained with the standard subcutaneous route employed simultaneously in a control group.¹⁴⁵ Moreover, local and systemic reactions following the intracutaneous vaccine were markedly fewer than those with subcutaneous vaccination. Weller, Cheever and Enders¹⁴⁶ have likewise obtained adequate antibody responses after intracutaneous vaccination. In view of the fact that influenza vaccination is probably in most instances actually a booster procedure,¹⁴⁷ and that intracutaneous immunization is in general highly effective as a booster agent in many conditions, there appears to be a strong case for use of this route as a general procedure.

Since the earliest studies on the virus of influenza, efforts have been made to immunize human beings by inhalation of active or inactive virus. The logic of such an approach is fortified by the finding that influenza virus combines directly with cells of the respiratory tract in a specific manner analogous to the well known reaction of the virus with erythrocytes.¹⁴⁸ The broad pathogenic significance of this reaction has recently been illuminatingly reviewed by Burnet.¹⁴⁹ A series of experimental studies by Australian workers, using the inhalatory route, showed that some immunity could be produced by influenza virus adsorbed in this fashion, but the results were not decisive.¹⁵⁰⁻¹⁵³ Francis and his co-workers¹⁵⁴ found that experimental infection with type B virus did not give staunch protection four months later and noted elsewhere that the results obtained by this method were inferior to those obtained with subcutaneous vaccination.¹⁵⁵ Henle and his associates¹⁵⁶ have made essentially similar observations. On the other hand, McLean and his co-workers¹⁵⁷ have observed a striking contrast in the antibody response induced in swine by experimental infection, as compared to parenteral vaccination. Comparable groups of swine were infected and compared with groups given one, two or three doses of formalinized virus vaccine.

An arbitrary scale was devised to measure the presence and severity of the infection induced by subsequent intranasal challenge with active virus. This scale gave a "morbidity score" of 88.6 in non-immune unvaccinated control animals. The morbidity score for all vaccinated animals averaged 58.9, whereas animals recently recovered from a primary infection experienced a morbidity score of only 16.7. These results suggest that, at least in swine, the protection achieved for a short period by infection far exceeds that induced by use of vaccine. Whether these findings can be translated into human protection remains to be seen, certainly, one must acknowledge the possibility that immunization by the respiratory route has potentialities greater than those of the parenteral route. However, immunity resulting from infection is still type specific, experiments in ferrets have shown that recent recovery from influenza A does not in any way increase resistance to influenza B, and vice versa.¹⁵⁵

Reactions

The widespread use of influenza vaccine during the past two years has provided extensive evidence that untoward reactions to the vaccine are not infrequent and can be particularly severe in children. Reactions have varied from local tenderness and swelling to severe, almost explosive (but transitory) febrile responses resembling influenza itself. The mechanism of these reactions is not wholly clear. Influenza virus has been shown to be toxic for animals,¹⁵⁹⁻¹⁶¹ but this toxicity disappears with inactivation of the virus, such as in the standard preparation of vaccine. Yet the particular severity of the reactions in children^{142, 162-164} suggests that a toxic factor is involved. As pointed out by Dingle⁹⁵ and Salk,¹⁶⁵ the reactions in human beings may be due to a combination of both toxic and sensitization factors. Whatever their cause, they have been sufficiently frequent and severe to stimulate reconsideration of the customary dosage employed.^{142, 162-164} In comparisons of the reactions induced by different vaccine preparations, it appeared that reactions to calcium-phosphate-adsorbed vaccine¹⁴² or protamine-precipitated vaccine¹⁴² were apparently milder than those induced by the standard red-cell eluate vaccine. However, such differences may have been due merely to differences in the inherent potencies of the vaccines.¹⁶⁶ Salk,¹⁶⁵ in an extensive study, found a very close correlation between the amount of virus injected and the severity of reaction produced. He concludes that, since increases in amounts of antigen used do not yield corresponding increases in antibody titers, the optimum dose of influenza virus should be no greater than that which will be reasonably well tolerated. This suggestion admittedly rests on the assumption that antibody titers and resistance to clinical influenza infection

until later childhood where the need for decreasing the susceptibility to influenza by inoculation with influenza vaccine is indicated,¹⁰¹ and others called attention to the value of such immunization for the aged, in view of the well established evidence¹⁰⁵ that the mortality from influenza tends to be highest in this group. The major emphasis was laid on vaccination before anticipated epidemics, in view of the evidence that influenza A recurred fairly regularly on a cycle of two or three years, and influenza B at intervals of four to six years.¹⁰⁶ However, interepidemic outbreaks¹⁰⁷ and even isolated cases¹⁰⁸ have been reported, so that a justification existed for use of influenza vaccine in interepidemic periods. Accordingly, vaccination against influenza was widely practiced during the catarrhal seasons of 1945-1946 and 1946-1947, in children,¹⁰⁹ industrial groups,¹¹⁰⁻¹¹² schools and colleges¹¹³⁻¹¹⁷ and the general population. The vaccine used was composed half of Type B (Lee strain), and half of Type A (equal parts of PR8 and Weiss strains). The results observed during the influenza A outbreak of February and March, 1947, were, to say the least, disappointing. Attack rates in one group were 54 per cent in the vaccinated compared to 49 per cent in the unvaccinated¹¹⁴, three other paired groups showed 7.19 per cent against 8.09 per cent,¹¹⁵ 20.2 per cent against 27.8 per cent,¹¹⁶ and 9.5 per cent in both groups.¹¹⁷ It was readily demonstrated in these and other studies¹¹⁸⁻¹²⁰ that the virus strain responsible for this outbreak, now widely known as the FM-1 strain, was antigenically quite distinct from the standard Type A strains employed in the vaccine although it was definitely a variant of Type A. It appears likely that a similar or perhaps identical strain caused the 1946-1947 influenza outbreak in England,¹²¹ during which three paired groups exhibited attack rates, in vaccinated and unvaccinated subjects respectively, of 11 per cent against 21 per cent, 11 per cent against 17 per cent, and 7.1 per cent against 8.3 per cent — surprisingly comparable to the rates simultaneously observed in the United States.

A few months after it was isolated, strain FM-1 was incorporated into the standard vaccine preparations, replacing the Weiss strain, which in turn had been included previously because it represented the common variant of its time. This sequence of periodic and unpredictable shifts in the antigenic pattern of influenza A virus has aroused some caution in evaluating the usefulness of vaccination. This attitude is reflected in the conservative conclusions of the 1947 report of the American Public Health Association study commission on influenza vaccination⁹⁷ and also in an editorial, which states, "One can only conclude that as yet influenza vaccination is in its experimental stage, and its widespread uncontrolled use as a routine measure does not seem justified."¹²²

Factors Affecting the Efficacy of Influenza Vaccine

Numerous investigators have described antigenic variations in influenza A virus, and two strains were isolated during the 1943-1944 epidemic that were definitely variants from the standard "A" pattern.¹²³⁻¹²⁴ Such variations may become the major problem in making influenza immunization effective. The persistence of variant strains of Type A influenza during the winter of 1947-1948 has provided opportunity to assess the value of the FM-1 strain in the currently available vaccine. The results are hard to evaluate. Meiklejohn and Bruyn¹²⁵ found essentially no antibody response to a locally isolated variant strain, in the serums of persons immunized with vaccine containing the FM-1 strain. On the other hand, Salk and Suriano¹²⁶ observed a definite reduction in the incidence of acute respiratory illness in persons receiving the "new" vaccine as compared with a control group receiving the "old" vaccine. Meanwhile, the possibility that further strain variants will arise is constantly present, and it is in large part for this reason that "listening posts" for early detection of new strains or new outbreaks of influenza have been set up on a nationwide and world-wide basis.¹²⁷ However, it has been pointed out¹²⁴ that the antigenic range of protection achieved by immunization might be broadened if the average antibody titer induced by the vaccine could be increased, since a rise in the titer to the homologous strain usually carries with it a comparable rise in the titers against related strains. Several possible methods of achieving the increase in titer have been explored. The simplest appears to be to concentrate the virus antigen. This has been effectively accomplished by centrifugation¹²⁸ and by alcohol precipitation,¹²⁹ both methods being designed primarily for purification, but yielding high concentrations of virus elementary bodies. It is indeed possible to increase the antibody response by increasing the dose of antigen,¹³⁰ but the gain is small in proportion to the stimulus applied, several workers having reported that a tenfold increase in the amount of antigen used gives an increase of only about two to two and a half times in antibody rise obtained.¹³¹⁻¹³³

Repeated inoculations of vaccine would ordinarily be expected to raise the antibody level above that obtained with one injection, were the response to influenza vaccine similar to that observed with diphtheria and tetanus toxoids and most other antigens. Although such increases in antibody titer have been observed in swine after repeat injections of swine influenza vaccine,¹³⁴ this has not been borne out in human experiments.¹³²⁻¹³⁵⁻¹³⁶ The extensive studies of Beard and his associates¹³⁷ in swine, however, suggest that the difference between success and failure may depend upon the interval between doses.

are generally closely correlated. It conflicts with the findings of Hare et al.,¹⁶⁷ who concluded that the antibody response was inadequate after anything less than a full dose of vaccine.

Considerable alarm has been expressed over the danger of true allergic reactions from inoculation of influenza vaccine, which is derived from the chorioallantoic fluid of the infected chick embryo. Two fatal reactions are reported to have occurred, in both of which a history of sensitivity to eggs was later traced. The apparently alarming possibilities inherent in the administration of egg proteins to a large number of human beings were reviewed by Ratner and Untracht,¹⁶⁸ who collected evidence suggesting that the problem was a widespread one. The report by Curphey,¹⁶⁹ of a death—said to have been allergic in nature—in a small child a few hours after an injection of influenza vaccine, and a similar report elsewhere¹⁷⁰ provided a basis for renewed caution in administering the vaccine. It is generally agreed that a history of possible sensitivity to egg protein should be carefully sought for, however, it is on record¹⁷¹ that many injections of vaccine have been given, without reaction, to persons with histories of mild egg sensitivity. A recent editorial¹⁷² has restated the widespread opinion that the risk of this type of reaction—slight as it is—might be reduced by further purification of the virus by the centrifuge¹⁷⁸ or alcohol¹⁷⁹ methods, thus eliminating most of the extraneous egg protein. However, a re-examination of the death reported by Curphey¹⁶⁹ suggests—as Salk¹⁷³ has pointed out—that it was due to a toxic rather than an allergic reaction. If such toxic deaths can indeed occur, the use of purified vaccines must be tempered with a caution against employing excessive quantities of virus, since the incidence of reactions rises sharply within a relatively narrow range of increase in virus concentration.¹⁶⁵

EDITH E. PARRIS, *Assistant Editor*

CASE 35271

PRESENTATION OF CASE

A forty-nine-year-old male cook was admitted to the hospital because of weakness, cough, chills and chest pain.

Six days before admission the patient noticed excessive fatigue. On the following day he developed anorexia, headache, dryness of the mouth, a light cough productive of whitish sputum with brownish streaks, and pain in the right anterior chest made worse by breathing. Four days before admission he had several shaking chills and the next day fatigue increased markedly. He developed pleuritic pains in the left anterior chest and had profuse sweats after ingestion of "red pills" that had been suggested by a druggist. Two days before admission the chest pain diminished, but over the following two days the cough became much worse, and since the day before admission the sputum had been streaked with red blood.

At twelve years of age he had had rheumatic fever and had been kept in bed for seventeen days. At twenty-one he had recurrent joint involvement after an upper respiratory infection. After he had recovered he had a tonsillectomy. For the past eighteen years his hip joints had bothered him intermittently, especially with weather changes. Sixteen months before admission he had seen several physicians because of easy fatigability, exertional dyspnea and occasional dyspnea at rest, and a slight cough. He was given digitalis and advised to reduce his activities. Two months later he was admitted to another hospital, where x-ray examination revealed an enlarged heart. He was advised to rest and to continue taking digitalis. He had never had ankle edema and no definite orthopnea. He had had gonorrhea five times between fourteen and twenty-four years before admission. On each occasion he was promptly treated and cured.

Physical examination revealed a well developed, well nourished, dyspneic man who appeared feverish and flushed. The skin was hot and moist. The tongue was coated and dry, and the throat red. The chest appeared normal, with good expansion. There were crackling rales, diminished breath sounds, and slight dullness to percussion in the right infrascapular area and over the right base posteriorly. The heart showed completely irregular rhythm with an apical rate of 104 and a radial pulse of 92. There were a Grade II apical systolic murmur and an apical mid-diastolic rumble. The left border of the heart appeared in normal position. The extremities were normal.

The temperature was 105°F, and the respirations 30. The blood pressure was 135 systolic, 55 diastolic.

Examination of the blood showed a red-cell count of 4,600,000 and a white-cell count of 6400, with

FIGURE 1

89 per cent neutrophils, 7 per cent lymphocytes and 4 per cent monocytes. The urinary sediment contained 2 to 5 red cells and 4 to 6 white cells per high-power field and occasional granular casts. A stool was normal. Sputum smears showed a few gram-positive streptococci. Repeated smears were negative for tubercle bacilli. The sputum culture showed no pneumococci.

An x-ray film of the chest (Fig. 1) showed mottled increased density occupying the whole upper half of the right-lung field and appearing to include only the right upper lobe. The hilar markings were slightly increased. The heart was prominent in the region of the left auricle and there was a prominence of the pulmonary artery.

The temperature continued at 103 to 104°F, and the respirations slowly rose over three days to a rate of 50. He was continued on digitalis and penicillin until the fourth day, when sulfadiazine was substituted for penicillin. A roentgenogram on the third day showed extension of the density to the right lower lobe and also involvement of the left lung (Fig 2). On the fourth day the respirations became more labored and rapid, and cyanosis and dyspnea increased. The lungs filled with coarse rhonchi, and large amounts of bright-red sputum

FIGURE 2

were raised. Early on the fifth day the respirations became very shallow, and the patient died.

DIFFERENTIAL DIAGNOSIS

DR ALLEN G. BRAILEY: I should like to see the x-ray films.

DR MILFORD D. SCHULZ: This first film was taken prior to the illness, it antedates it by three months and shows normal lungs. The heart is enlarged in the region of the left auricle. Films made at the time of hospital entry show a mottled area of increased density occupying the major portion of the right upper lobe that in two days extended to the lower right chest, and there is also involvement of the left chest. The mottling has become quite confluent. The lung roots are larger on the films made at the time of the illness than before, but at no time is there evidence of fluid in either pleural sinus.

DR BRAILEY: Would you make a diagnosis of rapidly advancing pneumonia from that picture?

DR SCHULZ: Yes, or pulmonary edema. If one saw the last film only, one would be tempted to think that it was pulmonary edema, especially in the face of the mitral disease.

DR BRAILEY: The significant features of this history are that a middle-aged cook with long-standing rheumatic heart disease died after eleven days of an acute febrile illness with symptoms largely confined to his chest. The causes of death that need to be seriously considered are acute fulminating tuberculosis, pneumonia of some type—perhaps embolic—and acute rheumatic infection. The bloodspitting and the x-ray appearance of his lungs make it desirable to mention tumor and bronchiectasis also, but these seem to be excluded by the acute febrile course. Certainly, if present, they must have been complicated by severe secondary infection.

It is obvious from the protocol that tuberculosis was seriously considered by the medical service. However, very rarely does tuberculosis, even in an explosive, pneumonic form, kill in so short a time. On the other hand, it might be argued that this man had a seriously damaged heart, which served to hasten his death. It is reported that repeated smears of sputum failed to show tubercle bacilli. This is a major point against the diagnosis but does not rule out the possibility. This man had had symptoms referable to his heart for many years, and he must have had previous x-ray examinations of his chest. Yet there is no mention that tuberculous lesions had ever been observed prior to his present illness. It is very unusual for tuberculosis to arise *de novo* in a man of forty-nine who has shown no x-ray evidence of previous infection. I cannot exclude tuberculosis, but I very much doubt if that will prove to be the anatomical diagnosis.

The diagnosis of pneumonia is not so easily disposed of. It is obvious that he had a pneumonic process of some kind in his chest, and his whole physical course is not inconsistent with pneumonia due to pneumococci or one of the other pyogenic organisms. The polymorphonuclear percentage is increased, and the low total white-cell count may only be a commentary on the severity of his infection. However, one should have no particular difficulty in finding and isolating the offending organism in pyogenic pneumonia, whereas we are told that pneumococci could not be grown from the sputum and only a few gram-positive streptococci were seen. Furthermore, most of the organisms that may provoke a fatal pneumonia are quite susceptible to adequate treatment with penicillin or sulfadiazine. Yet these agents were of no value to this patient. There are forms of pneumonia, very exotic in this locality, that could have produced this picture—such as melioidosis and pneumonias due to some of the rickettsias and coccidiomycetes. However, these conditions are so rare

in New England as to deserve hardly more than passing mention

His cough, his marked bloodspitting and his increasing dyspnea and cyanosis are all consistent enough with repeated pulmonary infarctions. But if he had a shower of pulmonary emboli, where did it come from? We are given no hint of phlebitis of any peripheral veins, although we know from sad experience that the source of emboli is often not recognized during life. His auricles were fibrillating, and the formation of thrombi in the auricles is a fairly common and dreaded complication of such fibrillation. It is quite possible that he developed a thrombus of the right auricle or appendage, which then shed emboli from time to time to plug branches of the pulmonary arteries. But it would be very remarkable, indeed, if these emboli all elected to lodge in the artery to the right upper lobe as the x-ray report suggests. And what about his fever? I think pulmonary infarction would scarcely give rise to temperatures of 103, and certainly not to 105°F, unless the emboli involved were infected. But septic emboli from the heart imply an acute bacterial endocarditis involving the tricuspid valve, and of such a rare lesion we have no hint. I cannot exclude the possibility, but I doubt if this man died of pulmonary embolism.

Finally, there exists the possibility that this man died of acute rheumatic fever and its complications. The literature contains a number of contributions purporting to show that rheumatic infection may, of itself, produce a pneumonitis distinguishable from other forms of pneumonia and from chronic passive congestion. There is as yet no general agreement that such an entity exists, but neither can the evidence be brushed easily aside. Those interested in the subject may well begin with a scholarly paper by J. R. Paul¹ and a more recent review by Seldin et al.² These, and other authors, point to a group of patients with a history of manifest rheumatic infection who are struck down with an illness of sudden onset, a temperature often of high level, a hacking cough, bloody sputum, marked dyspnea and cyanosis and usually a fatal outcome within ten to fourteen days. Onset with chills is rare. There may be transient pleurisy; physical signs of lung involvement are often minimal. The white-cell count is usually high (as it was not in the subject of this discussion). X-ray study may show involvement of one or of several lobes. Often, there is little to distinguish the x-ray picture from that of chronic passive congestion. Study of the sputum reveals no significant organisms and usually little pus. Frequently, the evidence of cardiac failure, as in our present case, is not impressive. The venous pressure and circulation time may be very little elevated, and the pulse rate and blood pressure may be well maintained. At post-mortem examination, the outstanding features appear to be the mononuclear and frankly hemorrhagic charac-

ter of the alveolar exudate, and attention is also called to a hyaline membrane lining the smaller bronchioles.

Whether these are features worthy to identify a separate clinical entity must lie outside this discussion. But it must be conceded that there are persons with a long-standing history of rheumatic infection who die as this man died — after a brief but stormy illness characterized by fever, cough, hemoptysis, rapidly increasing dyspnea, orthopnea and cyanosis with little evidence of heart failure but with evidence of a pneumonic process for which there is no readily apparent cause.

ANATOMICAL DIAGNOSES

Atypical viral pneumonia, fulminating
Rheumatic heart disease, with mitral stenosis

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN Autopsy showed rheumatic heart disease involving both the aortic and mitral valves, with a moderate degree of stenosis of the mitral valve. There was no evidence of superimposed bacterial endocarditis or of acute rheumatic endocarditis. The lungs were the interesting feature of this case. They were tremendous in size, the right lung weighing 2000 gm and the left, 1300 gm. Whenever one sees a lung weighing 2000 gm the first thing to think of is lobar pneumonia. On the other hand this did not look like lobar pneumonia. The cut surface revealed a spotty granularity and was extremely hemorrhagic. The right upper lobe was entirely consolidated, and the middle and lower lobes to a lesser degree. In the left lung the process was limited to a large area near the hilus involving a third to a half of each lobe. We cultured them and were unable to get any pneumococci or streptococci. We thought immediately of the fulminating influenza-virus pneumonia or rheumatic pneumonia.

Microscopical sections showed fairly acute pneumonia, bronchitis and interstitial pneumonitis, a condition that has been described in atypical viral pneumonia.^{3,4} There was infiltration of the alveolar walls as well as the alveoli themselves, more particularly around the bronchi, with polymorphonuclear leukocytes, fibrin and monocytes. The bronchioles were filled with organizing exudate. The atria and a large number of the alveoli were filled with blood, which was probably a secondary manifestation. The picture closely resembles sec-

The temperature continued at 103 to 104°F, and the respirations slowly rose over three days to a rate of 50. He was continued on digitalis and penicillin until the fourth day, when sulfadiazine was substituted for penicillin. A roentgenogram on the third day showed extension of the density to the right lower lobe and also involvement of the left lung (Fig. 2). On the fourth day the respirations became more labored and rapid, and cyanosis and dyspnea increased. The lungs filled with coarse rhonchi, and large amounts of bright-red sputum

FIGURE 2

were raised. Early on the fifth day the respirations became very shallow, and the patient died.

DIFFERENTIAL DIAGNOSIS

DR ALLEN G. BRAILEY: I should like to see the x-ray films.

DR MILFORD D. SCHULZ: This first film was taken prior to the illness, it antedates it by three months and shows normal lungs. The heart is enlarged in the region of the left auricle. Films made at the time of hospital entry show a mottled area of increased density occupying the major portion of the right upper lobe that in two days extended to the lower right chest, and there is also involvement of the left chest. The mottling has become quite confluent. The lung roots are larger on the films made at the time of the illness than before, but at no time is there evidence of fluid in either pleural sinus.

DR BRAILEY: Would you make a diagnosis of rapidly advancing pneumonia from that picture?

DR SCHULZ: Yes, or pulmonary edema. If one saw the last film only, one would be tempted to think that it was pulmonary edema, especially in the face of the mitral disease.

DR BRAILEY: The significant features of this history are that a middle-aged cook with longstanding rheumatic heart disease died after eleven days of an acute febrile illness with symptoms largely confined to his chest. The causes of death that need to be seriously considered are acute fulminating tuberculosis, pneumonia of some type—perhaps embolic—and acute rheumatic infection. The bloodspitting and the x-ray appearance of his lungs make it desirable to mention tumor and bronchiectasis also, but these seem to be excluded by the acute febrile course. Certainly, if present, they must have been complicated by severe secondary infection.

It is obvious from the protocol that tuberculosis was seriously considered by the medical service. However, very rarely does tuberculosis, even in an explosive, pneumonic form, kill in so short a time. On the other hand, it might be argued that this man had a seriously damaged heart, which served to hasten his death. It is reported that repeated smears of sputum failed to show tubercle bacilli. This is a major point against the diagnosis but does not rule out the possibility. This man had had symptoms referable to his heart for many years, and he must have had previous x-ray examinations of his chest. Yet there is no mention that tuberculous lesions had ever been observed prior to his present illness. It is very unusual for tuberculosis to arise *de novo* in a man of forty-nine who has shown no x-ray evidence of previous infection. I cannot exclude tuberculosis, but I very much doubt if that will prove to be the anatomical diagnosis.

The diagnosis of pneumonia is not so easily disposed of. It is obvious that he had a pneumonic process of some kind in his chest, and his whole physical course is not inconsistent with pneumonia due to pneumococci or one of the other pyogenic organisms. The polymorphonuclear percentage is increased, and the low total white-cell count may only be a commentary on the severity of his infection. However, one should have no particular difficulty in finding and isolating the offending organism in pyogenic pneumonia, whereas we are told that pneumococci could not be grown from the sputum and only a few gram-positive streptococci were seen. Furthermore, most of the organisms that may provoke a fatal pneumonia are quite susceptible to adequate treatment with penicillin or sulfadiazine. Yet these agents were of no value to this patient. There are forms of pneumonia, very exotic in this locality, that could have produced this picture—such as melioidosis and pneumonias due to some of the rickettsias and coccidiomyces. However, these conditions are so rare

and a quarter years. Two and a half years before admission, an x-ray film showed a shadow in the left upper lobe, and three months prior to admission a survey film confirmed the findings of the previous examination. That is of extreme importance. Apparently, there was no change over something more than two years. The right-angle telescopic lens was used in the upper lobes, and all we have is a visual report. So we do not know whether the mass was fixed or not, but it was round and smooth, seemed to be in two lobules and seemed to obstruct the bronchus completely. I assume that the collapsed area in the left upper lobe is the portion of the upper lobe that would be aerated through the bronchus that was obstructed by the visualized mass. Is that reasonable, Dr. Hanelin?

DR. HANELIN: I think the whole left upper lobe is reduced somewhat. It may be that the apical division is less aerated than the remainder.

DR. PITTMAN: We have a report of complete obstruction with no air in or out of it.

DR. HANELIN: It is possible, although unlikely, that the entire lobe is represented by the density that we see at the apex, the remainder of the lung being aerated by the lower lobe. The major fissure is not well demarcated.

DR. PITTMAN: Physical examination is not very helpful in this case. There are signs of some diminished tactile fremitus and occasional rales over the right-upper-lobe area, and I suppose that means the extreme upper chest. The diastolic pressure was high, with a nonenlarged heart, I cannot relate it to anything. The liver edge was two finger-breadths below the costal margin and fairly low. I doubt whether that is significant enlargement, and I assume that the rubbery prostate, which was three times the normal size, represented benign hypertrophy.

The blood on examination was fairly good with a hemoglobin of 12.5 gm. The white-cell count of 20,000, I assume, was a reflection of some infection in the lung. No sputum examination is noted. That is the story. He had been examined on the outside and following bronchoscopy came in for operation.

What was believed to be the matter and what was the preoperative diagnosis? If we go back to the very first line of this abstract it is stated that the patient was a wool spinner, and I think that means that one should stop and consider what particular things wool spinners might have. They might have dust carried in with the material they were spinning, although that gives an entirely different diffuse, bilateral picture and I do not think dust was important in this case. I suppose one must mention in the discussion of a patient who works with wool what we were taught in our youth about anthrax, it gives a pneumonic type of process and is acutely fatal. I believe that we do not have to consider it here.

From reading the record possibly one should give consideration to a foreign body that had been in

the bronchus for a long time and had become covered with tissue. I think that that is extremely far-fetched. One should have more sepsis. The fact that there is no history does not rule it out, but in a man of this age it makes it much less likely.

Then we come down, obviously, to a new growth, because here is a mass that occluded the lumen of a bronchus. First to consider is a malignant new growth. There had been no change in this man's x-ray films as far as we can tell for something over

FIGURE 1

two years. I cannot conceive of a bronchial carcinoma not progressing over a two-year period. In addition, this was a round, smooth mass. We do not know about fixation because it could not be touched. It was quite removed from the carina, but there was no widening or fixation of the carina, and if some lesion of that type had been present for over two years, it seems to me, there would have been extension that would have changed the appearance of the carina.

That brings me down to a benign intrabronchial lesion, which seems to me to fit this story best. The patient had nonspecific bronchial trouble. Probably, he had a good deal of blood streaking, which is extremely common in these tumors. He was not invalidated by his disease. Two and a half years or three years before admission he had enough trouble so that an x-ray film was taken but not enough trouble so that he was willing to follow advice, because as a result of the x-ray findings he was told that he should be hospitalized. He probably was not very sick. It seems to me that in a sixty-two-

tions that I found in our files of the old influenza epidemic of 1918, where the lungs were hemorrhagic and wet as these were. It is one of the few cases of atypical viral pneumonia that we have seen. Unfortunately, we did not have viral studies done on the material, so that we do not have actual proof of the diagnosis. There was 500 cc of fluid in the right pleural cavity at the time of autopsy, and a little under 100 cc on the left side.

DR BRAILEY: Were there any Aschoff bodies in the heart?

DR CASTLEMAN: No. We did consider rheumatic pneumonia, since this patient had a history of rheumatic infection. In rheumatic pneumonia as a rule one does not see so much cellular reaction, but rather a great many phagocytes and red cells. Also, the bronchi are usually not filled as these were. Of course, the whole question of rheumatic pneumonia is still a moot subject.

CASE 35272

PRESENTATION OF CASE

A sixty-two-year-old man, a wool spinner, entered the hospital because of hemoptysis.

For many years the patient had had "bronchial trouble," with cough, gradually increasing dyspnea and occasional blood-streaked sputum for three years. Two and a half years prior to admission an x-ray film revealed a shadow in the left upper lobe, and hospitalization for further study was advised. Instead he resorted to "heat treatments," with some improvement. Three months prior to admission an x-ray film taken in the course of a mass survey confirmed the findings on the previous examination, and a bronchoscopy was performed, with some alleviation of the cough but with aggravation of the hemoptysis. On bronchoscopy the trachea was deviated slightly to the right, as if from extrinsic pressure on the left side, the carina was in the midline, with no widening or fixation. The orifice of the left upper lobe, visualized through the right-angle telescopic lens, appeared to be completely occluded by a rounded, smooth mass, which seemed to be in two lobules. No air was seen to be passing in or out of the orifice. There was some reddening of the left main bronchus and left-lower-lobe bronchus. Following bronchoscopy the patient was scheduled for hospitalization.

On physical examination diminished tactile fremitus was present over the left upper lobe posteriorly, and occasional rales were heard over this area. The heart was not enlarged. The liver edge was palpable two fingerbreadths below the costal

margin. The prostate was enlarged to three times the normal size and was "rubbery."

The blood pressure was 180 systolic, 120 diastolic. Examination of the blood showed 12.5 gm of hemoglobin, with a white-cell count of 20,000. The specific gravity of the urine was 1.020, no albumin, sugar or acetone was present. The serum protein was 7 gm, and the nonprotein nitrogen was 36 mg per 100 cc. The prothrombin time was normal. An x-ray film of the chest, with fluoroscopy and a barium swallow, showed elevation of the left hilus, with some increased density of the left apex medially. There was a 1-cm, rounded area of density in the left first interspace anteriorly. The left upper lobe was decreased about a third in size (Fig 1). Elsewhere, the lung fields appeared clear. There was no evidence of pleural fluid. The esophagus was slightly deviated to the left at the level of the suprasternal notch. Just above this area there appeared to be slight compression of the trachea from the right, it was likewise slightly deviated to the left.

On the fourth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR HELEN S. PITTMAN: I hope Dr Hanelin is going to help me on this x-ray report. It confuses me. I wonder if we may see the films now.

DR JOSEPH HANELIN: These are spot films that show a part of the esophagus and also show the trachea quite well. I do not believe that the course of the esophagus, above the aortic arch, is particularly unusual. All the films of the chest were taken at the same time, or a day apart. I think the finding of greatest importance is evidence of collapse of the left upper lobe. The left hilus is elevated. There is diffuse increased density in the region of the apex, and there is an irregular area of density, about 1 cm in size, in the left first interspace. The esophagus and the trachea below the level of the arch are only questionably abnormal. It is possible that there is a greater degree of indentation along the left aspects of these structures, but I cannot be sure of it. The lungs elsewhere are clear. The heart is not enlarged. The aorta is elongated and tortuous.

DR PITTMAN: Is there any special compression of the trachea from the right?

DR HANELIN: The trachea follows a somewhat tortuous course. If this were to result from extrinsic pressure, the adjacent mass would be of most unusual contour.

DR PITTMAN: Then I am going to forget about it, because I do not know anything else to do about it that makes any sense.

The points that seem to me of interest and importance in this history are that this man, who had cough, increasing dyspnea and occasional blood-streaked sputum for years and who had an intra-bronchial mass, gave no history of ever having had a wheeze. He must have had a wheeze. There had apparently been no change over a period of two

Castration is one of the conditions of release of incorrigible male sex offenders (who as a civilized refinement, are refurnished with glass testicles), just as numbers of the inmates of mental-deficiency institutions have been sterilized before release.

year-old man, with a rather long history, minimal symptoms, repeated though apparently not very important hemoptysis, and in reasonably good health, the most logical explanation is a benign adenoma in the bronchus, the parenchymal lung disease representing collapse distal to the mechanical obstruction. I shall therefore make that my diagnosis.

DR DONALD S. KING: At one time it was believed that adenoma occurs more frequently in females than males. Dr. Ronald Sniffen has been working on these patients, and I think he has found the sex incidence to be about fifty-fifty.

DR PITTMAN: It still is that way in the literature—more frequent in females.

DR KING: But not in our series here.

DR PITTMAN: It also occurs in a slightly younger group than sixty-two years.

DR KING: I cannot remember having seen an adenoma in a man of sixty-two. We have also had epidermoid carcinomas recently that have hung on for a long time. I know the answer, but I agree that it seems as if this man was fairly well to have had a carcinoma.

DR J. G. SCANNELL: We arrived at the same point that Dr. Pittman did. We thought that the patient had a benign lesion of the bronchus, although we also considered carcinoma of the lung. In a man of sixty-two we decided to do a lobectomy, preserving as much lung as we could. At operation the tumor mass presented in the main left-upper-lobe bronchus, which was extremely short. It was therefore necessary to go closely around the tumor, leaving almost no free margin. The patient was dyspneic, and because of his age, unless there was an out-and-out malignant tumor, we believed that a pneumonectomy was not justified and relied on the benign character of an adenoma. I have forgotten whether or not we had a biopsy before operation.

DR TRACY B. MALLORY: Dr. Castleman did a frozen section during the operation, and I believe he reported adenoma.

DR HANELIN: How much was the left upper lobe reduced in size?

DR SCANNELL: It was not particularly reduced in size. The operative note says that the chest was opened, disclosing a somewhat collapsed left upper lobe, collapsed chiefly in the apical posterior segment.

CLINICAL DIAGNOSIS

Pulmonary tuberculosis

DR PITTMAN'S DIAGNOSES

Benign adenoma, left-upper-lobe bronchus

Collapse of left upper lobe, with chronic infection

ANATOMICAL DIAGNOSIS

Bronchial adenoma

PATHOLOGICAL DISCUSSION

DR MALLORY: The specimen we received in the laboratory showed an intrabronchial tumor. It was, as predicted, a benign adenoma, which had extended through the tracheal wall. Dr. Scannell, in his operative note, said it was shaped like a collar button, which is a common picture presented by this type of tumor. The upper segment of the lobe showed very extensive dense fibrosis, evidently the result of old organization of a pneumonitis. All the anatomical structures in that area had been rather thoroughly destroyed. The rest of the lobe was small and slightly collapsed.

DR PITTMAN: That probably was represented by the dense area on the film?

DR HANELIN: Yes.

DR MAHLON HOAGLAND: Would a tuberculoma be likely to produce such a picture?

DR PITTMAN: I have spent a good deal of time in the Treadwell Library, since I received this abstract, trying to find an intrabronchial tuberculoma but did not succeed. That is all I can say. That is why I did not mention it in my discussion.

DR SCANNELL: Have we had bronchial adenoma with satellite metastatic lymph nodes?

DR MALLORY: We have had only 1 in our series of cases and we have seen 1 or 2 specimens sent in from elsewhere in which satellite lymph nodes were involved, but never a case with generalized metastasis, although they have been reported in cases in which there is no reason to question the diagnosis.

DR HOAGLAND: Were any lymph nodes removed with this specimen?

DR MALLORY: Yes, but they were anthracotic and did not contain tumor.

DR SCANNELL: The term "adenoma" has bothered me because as I understand it, it is not a gland-forming tumor—just a pseudo-adenoma really.

DR MALLORY: This present tumor resembled a true adenoma, however, rather more than some do. There were in a few areas cells producing mucin, which is an unusual phenomenon, but I still believe there is no doubt that it should be classified as a benign tumor. The most characteristic of these tumors resemble very closely the histologic structure of carcinoid tumors of the appendix and small intestine. The majority of carcinoids remain localized, a few involve regional lymph nodes, and a very small proportion metastasize. Generally both tumors share this characteristic low grade of malignancy. A second group of tumors likewise usually classed as bronchial adenomas have the histologic features of some of the better differentiated basal-cell tumors of the skin.

ing or deceased partner to the remaining partners" Provision is made for partners who originally staved out of the Service because of the lack of these new safeguards, to join it for the first two months after the passage of the Bill and receive compensation for the good will of their practices

Various other amendments to the Act give substance to the promises that had been made—promises that last year were instrumental in finally inducing a majority of the medical profession to accept the terms of employment established under the Act

There have been many warnings regarding the harm that British physicians believe medical practice has suffered as a result of the Act. The Amending Bill appears as evidence of good faith on the part of the Ministry to make the practice of medicine as acceptable as possible to all who are concerned with it. The *British Medical Journal*, mouthpiece of the British Medical Association, takes a somewhat different attitude. Many more matters were to have been included in the Amending Bill, and in their omission the Minister has failed to fulfil his promise to discuss their inclusion with the medical profession. "He has again committed a breach of trust," the *Journal* insists, "with a profession that has loyally collaborated with the Government in operating a Service full of imperfections." A final answer cannot yet be given to the question whether governmental control of medicine can in any way be made compatible with reasonable efficiency and economy

IN HOC SIGNO

THE leopard, according to a remote biologic authority, can no more change his spots than can the Ethiopian his skin. The allusion, however, put originally in the form of a question, applies only to the individual and to a pre-Darwinian concept of the nature of things, change is inherent in all life and that form of life can survive the longest that can best adapt itself to its changing environment

So it is with journalism, which, like lava, frequently the result of an explosive eruption, must remain fluid if it expects to get anywhere

The *New England Journal of Medicine*, as a familiar example, has changed a number of its spots in its hundred-odd years of existence. Its changes have been gradual, however, as considered changes should be, perhaps its progress may be likened to that of a glacier rather than a stream of lava, and certainly the melting glacier gives off many streams of water whereas the lava carries only destruction in its teeth

In the files of the *Journal* a distinguished ancestry lies preserved. The *New England Journal of Medicine and Surgery and the Collateral Branches of Science*, "Conducted by a Number of Physicians," was first proposed by Dr John Collins Warren and made its initial appearance in January, 1812, the leading article consisting of "Remarks on Angina Pectoris" by John Warren

In 1823 *The Boston Medical Intelligencer*, a weekly publication, appeared, conducted by Jerome V C Smith. It contained "Extracts from Foreign and American Journals, A Variety of Local Intelligence on Subjects Connected with Medicine, Biographical Sketches of Distinguished Surgeons and Physicians, Descriptions of the Principal Hospitals in Europe, Original Articles on Various Diseases, with Concise Views of the Improvements and Discoveries in the Medico-Chirurgical Sciences"

The charms of the *Intelligencer* completely overcame the *New England Journal of Medicine and Surgery*. After a short courtship they were united in February, 1828, the synchronous result of the union being the *Boston Medical and Surgical Journal*, born on the nineteenth day of the same month

Many changes in type, format and substance, but never a lapse in virtue, marked the peaceful, century-long progress of the *Boston Medical and Surgical Journal*. Of these changes the latest were its acquisition by the Massachusetts Medical Society in 1921, and the assumption of its present title in 1928. The *New England Journal of Medicine* has itself undergone conservative changes. The type has been improved, both of the text and of the title. The cover has gone mildly into the red, even if only on alternate weeks. Other minor alterations have

not for eugenic reasons but in order that they may re-enter society without increasing society's burdens

In view of the exposé of current penal methods that has been revealed to the citizens of Massachusetts in recent months, the penal code of Denmark has much to recommend it

STRANGE BEDFELLOWS

BRITAIN'S "most noted radiologist," according to Bulletin No 429 of the Citizens Medical Reference Bureau Inc, of 1860 Broadway, New York City, is opposed to mass x-ray checkups. In the words of Dr James F Brailsford, founder of the British Radiological Association and director of the x-ray and radium departments at Birmingham Hospital, as reprinted from the Los Angeles *Times*:

If you feel fit and well, stay away from all doctors. Even in the case of cancer, nature will notify educated persons when to seek medical advice. Mass x-ray examinations for tuberculosis and cancer do more harm than good. Periodic examinations of those who have no symptoms of tuberculosis and cancer are of doubtful value.

"Most people know it when they have cancer," according to Dr Brailsford's novel creed. "The trouble is that even doctors, knowing they have cancer, keep quiet until too late. However, if people will seek advice when they feel sick and not worry when they feel well, lives, money and time will be saved."

The distinguished visitor from Great Britain, who expressed his views as quoted above to a group of physicians at the Hollywood Presbyterian Hospital, is undeniably entitled to his own opinions and the right to express them. It is unfortunate, however, that opinions so contrary to those held by the majority of conscientious physicians should receive any widespread publicity.

The secretary of the Citizens Medical Reference Bureau, Inc, which has so quickly rallied to Dr Brailsford's unique standard, states, in reply to a request for information, that this organization is a lay one, having for its purpose, "To preserve, establish, maintain and safeguard through publicity and other lawful means, the right of adults or, in the case of minors, the right of parents or guardians to determine the form or manner of treatment or

care to be prescribed or applied for the cure or prevention of disease."

Certain of the objectives of the Citizens Medical Reference Bureau are undoubtedly praiseworthy. Where it loses its perspective and departs from its apparently laudable purpose is in maintaining for a primary object not the protection of the rights of the majority to enjoy, so far as possible, freedom from exposure to disease, but what it considers to be the right of the individual to escape vaccination and any other compulsory measures that are designed to prevent him from becoming a menace to the public. What citizens of this type invariably fail to understand is the necessity, in a working democracy, for all members of society to surrender certain personal liberties the exercise of which may jeopardize the common good.

The members of Citizens Medical Bureau, Inc, like those friendly foes of medical practice, the Christian Scientists, happen at the moment to be aligned with the medical profession in its opposition to compulsory health insurance.

Politics makes strange bedfellows, even if only for a night.

GREAT BRITAIN'S AMENDING BILL

ENGLAND'S Minister of Health has submitted to Parliament his promised bill for amending the National Health Service Acts of 1946 and 1947. "Let it be said at once," the *Lancet*¹ reports, "that the Minister has fully kept faith, for all the promises made a year ago are here translated into legal form."

The manner in which a general practitioner may be remunerated is safeguarded by a clause that makes it impossible to change this remuneration by regulation and to make it consist wholly or mainly of a fixed salary without reference to the number of patients for whom he has agreed to provide services. Clause 11 bans any requirement that all specialists employed for the purpose of hospital and specialist services shall be employed whole time.

The position of partnerships and the transfer of practices is clarified, "and appropriate methods are provided for transferring the share of a partner-

MISCELLANY

BOSTON UNIVERSITY ORGANIZES DEPARTMENT OF LEGAL MEDICINE

Dr Walter Jetter, pathologist for the Massachusetts Department of Mental Health and assistant professor of legal medicine at Harvard Medical School, has been selected by the trustees of Boston University to head a new department of legal medicine at Boston University School of Medicine. He will assume his new duties on July 1.

Dr Jetter was born in Buffalo, New York, on September 4, 1905. He received his M.D. degree from the University of Buffalo School of Medicine in 1931 and his M.S. in medicine in 1938 from the same school.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Ärztliche Rheokardiographie By Wolfgang Holzer and Kurt Polzer. 8° paper, 144 pp., with 88 illustrations and 3 tables. Vienna: Verlag Wilhelm Maudrich, 1948. \$5.00. *Bücher der physikalischen Medizin*. Volume III.

This monograph is comprehensive in scope, discussing the method in general, animal experimentation and the normal rheocardiogram in man, and in diseased conditions of the heart. The pertinent literature is noted throughout the text, which is concluded with an extensive bibliography of sources mentioned in the text and dating to 1947. There is a good index. The material is well arranged. The monograph is well published in a typical German style. It should be available to all persons interested in cardiology.

Bacterial and Mycotic Infections of Man. Edited by Rene J. Dubos, Ph.D., The Rockefeller Institute for Medical Research. 4° cloth, 785 pp., with 101 illustrations, including 3 plates in color. Philadelphia: J. B. Lippincott Company, 1948. \$5.00.

This comprehensive treatise on medical bacteriology is a companion volume to *Viral and Rickettsial Infections of Man*, edited by Dr. Thomas M. Rivers and published by Lippincott in 1948. Thirty-four authors collaborated in the production of the volume. The beginning chapters deal with general principles and are followed by discussions of the various bacteria, spirochetes and mycoses. The concluding chapters are devoted to sterilization, chemotherapy, epidemiology and the cultivation and identification of pathogenic bacteria. The material is well arranged. There are lists of selected references appended to the various chapters. The text is concluded with comprehensive indexes of authors and subjects. The book is well published but since it weighs nearly 5 pounds a lighter paper, if possible, should have been used. This should be considered an essential reference book for all medical libraries and should be available to all persons interested in bacteriology and bacterial diseases.

The Digestive Tract in Roentgenology. By Jacob Buckstein, M.D., assistant professor of clinical medicine, Cornell University Medical College, visiting roentgenologist (alimentary-tract division), Bellevue Hospital, New York City, attending gastroenterologist, Beth David Hospital, New York City, and consultant in gastroenterology, Central Islip State Hospital, New York. 4° cloth, 889 pp., with 1030 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$16.00.

This treatise is based on the author's experience of twenty-five years at Bellevue Hospital, where an enormous amount of material was available, and also on his private practice as a gastroenterologist. The material is well arranged. Selected lists of references are appended to the various chapters. The pertinent literature is reviewed in each special chapter. Indexes of authors and of subjects are referred to throughout the text. The volume is well published and is recommended as a standard reference work for all medical libraries and to all roentgenologists.

Viral Diseases of Man. By C. E. van Rooven, M.D., D.Sc. (Edin.), M.R.C.P. (Lond.), research member and professor of virus infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto, and A. J. Rhodes, M.D., F.R.C.P. (Edin.), research associate and professor of virus infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto and consultant in virus infections, Hospital for Sick Children, Toronto. 8° cloth, 1202 pp., with 43 illustrations. New York: Thomas Nelson and Sons, 1948. \$22.50.

This edition of a standard reference work first published in 1940 has been thoroughly revised in the light of the knowledge of the subject gained during the past ten years. The literature has been surveyed through 1947 with the addition of some papers published during the early months of 1948. Selected references are appended to each chapter. The latest information on two diseases prevalent in the United States—influenza and poliomyelitis—is given at length. All the diseases now attributed to viruses are discussed in detail. The type and printing are good but the use of a coated paper making the volume weigh more than 5 pounds is not justified by the few illustrations. The book should be in all medical libraries and should be available to all general practitioners.

The Common Sense Psychiatry of Dr. Adolf Meyer. Fifty-two selected papers edited with biographical narrative by Alfred Lief. 8° cloth, 677 pp. New York: McGraw-Hill Book Company, Inc., 1948. \$6.50.

This volume constitutes a collection of fifty-two papers of Dr. Meyer brought together from scattered sources and reprinted in one volume for convenience for reference purposes. A short biographic sketch precedes the papers. A glossary and an index conclude the volume. The publishing is excellent. The book is recommended for all medical libraries and should be available to all psychiatrists.

Handbook of Medicine for Final Year Students. By G. F. Walker, M.D., M.R.C.P. (Lond.), consulting physician, Peterborough Memorial Hospital. Fourth edition. 12° cloth, 308 pp. London: S. & S. W. Publications Ltd. 1948. 25s.

This manual, first published in 1931 and now in its fourth edition, has been thoroughly revised and brought up to date. It covers the whole field of medicine and naturally reflects the British point of view. The small volume is well published.

Occupational Therapy Source Book. Edited by Sidney Licht, M.D., with an introduction by C. Charles Burlingame, M.D., psychiatrist-in-chief, The Institute of Living. 4° cloth, 90 pp. Baltimore: Williams and Wilkins Company, 1948. \$1.00.

Dr. Licht has brought together in this volume ten extracts on occupational therapy in mental diseases from the works of pioneers in the field of psychiatry ranging from Pinel (1801) to Reid (1914). Other authors represented and the dates of their publications are Reil (1803), Hallaran (1810), Benjamin Rush (1812), Tuke (1816), Esquirol (1838), Leuret

been recommended by the experts and are going into effect with the current volume a weekly index of our loyal advertisers, and an insignia, adopted after much deliberation, that is truly representative of the *Journal* itself and its distinguished, if somewhat provincial, ancestry. The final form of the seal now appearing on the cover was suggested and drafted by Dr. Harold Bowditch.

In hoc signo vinces or — something like that!

It would be absolute madness, indeed, to trust a confirmed cholera patient to a few drops of camphor spirits, or three grains of *sulphur* and charcoal.

He who depends

Upon such favors, swims with fins of lead,
And hews down oaks with rushes

Boston M & S J, July 4, 1849

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

WOOD-TICK STUDY IN 1949

Some further progress will be made on the wood-tick study during the present season, although it was not possible to get into the field when the ticks first emerged, because funds had not been made available.

The funds that will be used this year represent the small balance left over from the study authorized in 1948. They will be used largely in determination of the results of spraying by other agencies in areas where ticks are prevalent, since it will not be possible for the Department to do any spraying studies this year with the small amount of funds. It is expected that the Legislature will make additional funds available for studies to be carried out in 1950. If so, experiments on the control can be begun as soon as the ticks begin to emerge from hibernation in order to study how long sprays will be effective in keeping down the tick population.

The Department is very much interested in receiving information from any persons or organizations that attempt to control ticks by sprays during the present season. It wishes to have on hand the best information regarding the possible methods of control so that those who expend their funds for the purpose will derive the greatest benefit from their operations.

The Department is particularly anxious to obtain information and receive specimens of ticks found inland more than fifteen miles from the seacoast. Up to the present time most of the tick-infested areas have been located near the coast.

UNUSUAL SEROLOGIC TESTS

Some of the unusual serologic tests formerly performed at the National Institutes of Health are now being done entirely at the Communicable Disease Center in Georgia. These are tests for amebiasis, trichinosis, echinococcosis and leptospirosis. Specimens for these tests should hereafter be sent to the Immunology-Serology Laboratory, Communicable Disease Center, United States Public Health Service, Chamblee, Georgia.

Blood specimens for serologic tests for trypanosomiasis, schistosomiasis, filariasis, leishmaniasis and toxoplasmosis should still be sent to the Laboratory of Tropical Diseases, National Institutes of Health, Bethesda 14, Maryland.

COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MAY, 1949

DISEASE	RESUME		
	MAY 1949	MAY 1948	SEVEN YEAR MEDIAN
Chancroid	4	2	2*
Chicken pox	2233	1612	1763
Diphtheria	42	14	16
Dog bite	1472	1237	1269
Dysentery bacillary	4	8	8
German measles	1243	132	381
Gonorrhea	254	218	340
Granuloma inguinale	0	0	0*
Lymphogranuloma venereum	0	2	2*
Malaria	2	1	12
Measles	2327	5743	3320

Whooping cough	389	132	537

* Five-year median

COMMENT

Diseases above the seven-year median were chicken pox, diphtheria, German measles, poliomyelitis and typhoid fever. Diseases below the seven-year median were measles, meningitis, mumps, scarlet fever and whooping cough.

Diphtheria continued to be unusually prevalent, remaining at the level of fifteen years ago for this season. The incidence of poliomyelitis was the highest for May since 1935, but 6 of the cases were widely scattered along the seacoast. German measles continued its upward trend, suggesting that the next season may bring an epidemic.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Beverly, 1, Boston, 2, Cambridge, 6, Canton, 1, Malden, 2, New Bedford, 1, Newton, 1, Shirley, 1, Somerville, 1, Winthrop, 1, total, 4. Dysentery, bacillary, was reported from Pittsfield, 1, Waltham, 2, Winthrop, 1, total, 4.

Encephalitis, infectious, was reported from Lowell, 1, Rehoboth, 1, Sterling, 1, total, 3.

Infectious hepatitis was reported from Lowell, 1, Norwood, 1, Wrentham, 2, total, 4.

Malaria was reported from Lowell, 1, Swampscott, 1, total, 2.

Meningitis, meningococcal, was reported from Agawam, 1, Boston, 1, Lawrence, 1, Needham, 1, total, 4.

Meningitis, Pfeiffer bacillus, was reported from Brockton, 1, total, 1.

Meningitis, staphylococcus, was reported from Wrentham, 1, total, 1.

Meningitis, undetermined, was reported from Arlington, 1, Brockton, 1, Taunton, 1, total, 3
 Poliomelitis was reported from Arlington 1, Braintree 1, Brookline, 1, Cambridge, 1, Milton, 4, Newbury 1, Wareham, 1, total, 10
 Salmonellosis was reported from Leominster, 1, Peabody 1, total, 2
 Septic sore throat was reported from Boston, 2, Lynn, 1, Worcester, 1, total, 4
 Typhoid fever was reported from East Longmeadow 1, Everett, 2, Leominster, 1, Peabody, 1, Somerville 1, total 6
 Typhus fever was reported from Boston, 1, total 1
 Undulant fever was reported from Boxboro, 1, Maynard 1, Natick, 1, Pepperell, 1, total, 4

MISCELLANY

BOSTON UNIVERSITY ORGANIZES DEPARTMENT OF LEGAL MEDICINE

Dr Walter Jetter, pathologist for the Massachusetts Department of Mental Health and assistant professor of legal medicine at Harvard Medical School, has been selected by the trustees of Boston University to head a new department of legal medicine at Boston University School of Medicine. He will assume his new duties on July 1.

Dr Jetter was born in Buffalo, New York, on September 4, 1905. He received his M.D. degree from the University of Buffalo School of Medicine in 1931 and his M.S. in medicine in 1938 from the same school.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Ärztliche Rheokardiographie. By Wolfgang Holzer and Kurt Polzer. 8°, paper, 144 pp., with 88 illustrations and 3 tables. Vienna: Verlag Wilhelm Maudrich, 1948. \$3.00. *Bücher der physikalischen Medizin*. Volume III.

This monograph is comprehensive in scope, discussing the method in general, animal experimentation and the normal rheocardiogram in man, and in diseased conditions of the heart. The pertinent literature is noted throughout the text, which is concluded with an extensive bibliography of sources mentioned in the text and dating to 1947. There is a good index. The material is well arranged. The monograph is well published in a typical German style. It should be available to all persons interested in cardiology.

Bacterial and Mycotic Infections of Man. Edited by René J. Dubos, Ph.D., The Rockefeller Institute for Medical Research. 4°, cloth, 785 pp., with 101 illustrations, including 3 plates in color. Philadelphia: J. B. Lippincott Company, 1948. \$5.00.

This comprehensive treatise on medical bacteriology is a companion volume to *Viral and Rickettsial Infections of Man*, edited by Dr. Thomas M. Rivers and published by Lippincott in 1948. Thirty-four authors collaborated in the production of the volume. The beginning chapters deal with general principles and are followed by discussions of the various bacteria, spirochetes and mycoses. The concluding chapters are devoted to sterilization, chemotherapy, epidemiology and the cultivation and identification of pathogenic bacteria. The material is well arranged. There are lists of selected references appended to the various chapters. The text is concluded with comprehensive indexes of authors and subjects. The book is well published but since it weighs nearly 5 pounds a lighter paper, if possible, should have been used. This should be considered an essential reference book for all medical libraries and should be available to all persons interested in bacteriology and bacterial diseases.

The Digestive Tract in Roentgenology. By Jacob Buckstein, M.D., assistant professor of clinical medicine, Cornell University Medical College, visiting roentgenologist (alimentary tract division), Bellevue Hospital, New York City, attending gastroenterologist, Beth David Hospital, New York City and consultant in gastroenterology, Central Islip State Hospital, New York. 4°, cloth, 889 pp., with 1030 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$16.00.

This treatise is based on the author's experience of twenty years at Bellevue Hospital, where an enormous amount of material was available, and also on his private practice as a gastroenterologist. The material is well arranged and lists of references are appended to the various chapters. The pertinent literature is reviewed in each special chapter. Indexes of authors and of subjects are referred to throughout the text. The volume is well published and is recommended as a standard reference work for all medical libraries and to all roentgenologists.

Selected Diseases of Man. By C. E. van Rooven, M.D., D.Sc., F.R.C.P. (Lond.), research member and professor of virus infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto and A. J. Rhodes, M.D., F.R.C.P. (Edin.), research associate and professor of virus infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto and consultant in virus infections, Hospital for Sick Children, Toronto. 8°, cloth, 1202 pp., with 43 illustrations. New York: Thomas Nelson and Sons, 1948. \$22.50.

This edition of a standard reference work first published in 1940 has been thoroughly revised in the light of the knowledge of the subject gained during the past ten years. The literature has been surveyed through 1947 with the addition of some papers published during the early months of 1948. Selected references are appended to each chapter. The latest information on two diseases prevalent in the United States—influenza and poliomyelitis—is given at length. All the diseases now attributed to viruses are discussed in detail. The type and printing are good, but the use of a coated paper making the volume weigh more than 5 pounds, is not justified by the few illustrations. The book should be in all medical libraries and should be available to all general practitioners.

The Commonsense Psychiatry of Dr. Adolf Meyer. Fifty-two selected papers edited, with biographical narrative, by Alfred Lief. 8°, cloth, 677 pp. New York: McGraw-Hill Book Company, Inc., 1948. \$6.50.

This volume constitutes a collection of fifty-two papers of Dr. Meyer brought together from scattered sources and reprinted in one volume for convenience for reference purposes. A short biographic sketch precedes the papers. A glossary and an index conclude the volume. The publishing is excellent. The book is recommended for all medical libraries and should be available to all psychiatrists.

Handbook of Medicine for Final Year Students. By G. F. Walker, M.D., M.R.C.P. (Lond.), consulting physician, Peterborough Memorial Hospital. Fourth edition. 12°, cloth, 308 pp. London: S. K. & S. P. Publications Ltd., 1948. 25s.

This manual, first published in 1931 and now in its fourth edition, has been thoroughly revised and brought up to date. It covers the whole field of medicine and naturally reflects the British point of view. The small volume is well published.

Occupational Therapy Source Book. Edited by Sidney Licht, M.D., with an introduction by C. Charles Burlingame, M.D., psychiatrist-in-chief, The Institute of Living. 4°, cloth, 90 pp. Baltimore: Williams and Wilkins Company, 1948. \$1.00.

Dr. Licht has brought together in this volume ten extracts on occupational therapy in mental diseases from the works of pioneers in the field of psychiatry ranging from Pinel (1801) to Reid (1914). Other authors represented and the dates of their publications are Reil (1803), Hallaran (1810), Benjamin Rush (1812), Tuke (1816), Esquirol (1838), Leuret

(1840), Voisin (1843) and Kirkbride (1880). The paper of Dr. Reid on "ergotherapy in the treatment of mental disorders" was originally published in the *Boston Medical and Surgical Journal*. The extracts are preceded by a long outline of the early history of occupational therapy, dating from the Hippocratic era to 1915, written by Dr. Licht. The volume is well published, and the price is very reasonable. The book should be in all medical libraries, in all medical-history collections and in the collections of persons interested in the subject.

Pediatrics and the Emotional Needs of the Child As discussed by pediatricians and psychiatrists at Hershey, Pennsylvania, March 6-8, 1947. Edited by Helen I. Witmer. 8°, paper, 180 pp., with 17 illustrations. New York: Commonwealth Fund, 1948. \$1.50.

This conference was participated in by 48 physicians and social workers. The various aspects of the subject were discussed in detail in five meetings. An appendix comprises reports from the psychiatric services or child-guidance clinics of ten prominent hospitals. The volume is well published and should be in all collections on pediatrics, psychiatry and applied psychology. It should prove useful to social workers.

An Introduction to Surgery. By Rutherford Morison, M.D., F.R.C.S. Edin., F.R.C.S. Eng., M.A., D.C.I., LL.D., and Charles F. M. Saint, C.B.E., M.D., M.S., F.R.C.S., F.R.A.C.S. Fourth edition. 8°, cloth, 330 pp., with 304 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$10.00.

This small manual, designed for the student of surgery, was revised and brought up to date by Dr. Saint after the death of Dr. Morison. It constitutes on the whole a short work on surgical pathology. The material is well organized, and the text well illustrated. The printing was done in Great Britain, and the publishing is excellent.

A M.A. Interns' Manual. 12°, cloth, 201 pp. Philadelphia: W. B. Saunders Company, 1948. \$2.25.

This small volume was originally published in 1938 under the present title. It was the successor to *Hospital Practice for Internes*, first published in 1932. The text has been prepared by the various councils of the Association, and is divided into seven principal sections, as follows: internships and residencies — general information, clinical and laboratory data, including common emergencies, drug administration, materia medica — useful drugs, acute poisoning (diagnosis and treatment), diet and nutrition and physical medicine. Parts two to seven supply the intern with the essential facts needed in his daily practice. The eighth part, the "Lawful Scope of Intern Practice," is an important contribution on the legal status of interns in the various states. The last part is a short description of the American Medical Association and its subdivisions. There is an index. The publishing is excellent. The book should prove exceedingly useful to all interns.

NOTICES

MASSACHUSETTS TRUDEAU SOCIETY

At a meeting of the Massachusetts Trudeau Society on June 9, the following officers were elected: president, Henry D. Chidwick, of Waltham; vice-president, Francis P. Dawson, of Waltham; and secretary-treasurer, Edward J. Welch, of Brookline.

MEDICAL SCIENCE UNDER DICTATORSHIP

LEO ALEXANDER M.D.*

BOSTON

SCIENCE under dictatorship becomes subordinated to the guiding philosophy of the dictatorship. Irrespective of other ideologic trappings, the guiding philosophic principle of recent dictatorships, including that of the Nazis, has been Hegelian in that what has been considered "rational utility" and corresponding doctrine and planning has replaced moral, ethical and religious values. Nazi propaganda was highly effective in perverting public opinion and public conscience, in a remarkably short time. In the medical profession this expressed itself in a rapid decline in standards of professional ethics. Medical science in Nazi Germany collaborated with this Hegelian trend particularly in the following enterprises: the mass extermination of the chronically sick in the interest of saving "useless" expenses to the community as a whole, the mass extermination of those considered socially disturbing or racially and ideologically unwanted, the individual, inconspicuous extermination of those considered disloyal within the ruling group, and the ruthless use of "human experimental material" for medicomilitary research.

This paper discusses the origins of these activities, as well as their consequences upon the body social, and the motivation of those participating in them.

Preparatory Propaganda

Even before the Nazis took open charge in Germany, a propaganda barrage was directed against the traditional compassionate nineteenth-century attitudes toward the chronically ill, and for the adoption of a utilitarian, Hegelian point of view. Sterilization and euthanasia of persons with chronic mental illnesses was discussed at a meeting of Bavarian psychiatrists in 1931.¹ By 1936 extermination of the physically or socially unfit was so openly accepted that its practice was mentioned incidentally in an article published in an official German medical journal.²

Lay opinion was not neglected in this campaign. Adults were propagandized by motion pictures,

*Instructor in psychiatry, Tufts College Medical School, director, Neurobiologic Unit, Division of Psychiatric Research, Boston State Hospital, formerly consultant to the Secretary of War, on duty with the Office of the Chief of Counsel for War Crimes, Nuremberg, United States Zone of Germany 1946-1947.

one of which, entitled "I Accuse," deals entirely with euthanasia. This film depicts the life history of a woman suffering from multiple sclerosis, in it her husband, a doctor, finally kills her to the accompaniment of soft piano music rendered by a sympathetic colleague in an adjoining room. Acceptance of this ideology was implanted even in the children. A widely used high-school mathematics text, "Mathematics in the Service of National Political Education,"³ includes problems stated in distorted terms of the cost of caring for and rehabilitating the chronically sick and crippled. One of the problems asked, for instance, how many new housing units could be built and how many marriage-allowance loans could be given to newly wedded couples for the amount of money it cost the state to care for "the crippled, the criminal and the insane."

Euthanasia

The first direct order for euthanasia was issued by Hitler on September 1, 1939, and an organization was set up to execute the program. Dr. Karl Brandt headed the medical section, and Phillip Bouhler the administrative section. All state institutions were required to report on patients who had been ill five years or more and who were unable to work, by filling out questionnaires giving name, race, marital status, nationality, next of kin, whether regularly visited and by whom, who bore financial responsibility and so forth. The decision regarding which patients should be killed was made entirely on the basis of this brief information by expert consultants, most of whom were professors of psychiatry in the key universities. These consultants never saw the patients themselves. The thoroughness of their scrutiny can be appraised by the work of one expert, who between November 14 and December 1, 1940, evaluated 2109 questionnaires.

These questionnaires were collected by a "Realm's Work Committee of Institutions for Cure and Care."⁴ A parallel organization devoted exclusively to the killing of children was known by the similarly euphemistic name of "Realm's Committee for Scientific Approach to Severe Illness Due to Heredity and Constitution." The "Charitable

Transport Company for the Sick" transported patients to the killing centers, and the "Charitable Foundation for Institutional Care" was in charge of collecting the cost of the killings from the relatives, without, however, informing them what the charges were for, in the death certificates the cause of death was falsified.

What these activities meant to the population at large was well expressed by a few hardy souls who dared to protest. A member of the court of appeals at Frankfurt-am-Main wrote in December, 1939

There is constant discussion of the question of the destruction of socially unfit life—in the places where there are mental institutions, in neighboring towns, sometimes over a large area, throughout the Rhineland, for example. The people have come to recognize the vehicles in which the patients are taken from their original institution to the intermediate institution and from there to the liquidation institution. I am told that when they see these buses even the children call out "They're taking some more people to be gassed." From Limburg it is reported that every day from one to three buses with shades drawn pass through on the way from Weilmünster to Hadamar, delivering inmates to the liquidation institution there. According to the stories the arrivals are immediately stripped to the skin, dressed in paper shirts, and forthwith taken to a gas chamber, where they are liquidated with hydrocyanic acid gas and an added anesthetic. The bodies are reported to be moved to a combustion chamber by means of a conveyor belt, six bodies to a furnace. The resulting ashes are then distributed into six urns which are shipped to the families. The heavy smoke from the crematory building is said to be visible over Hadamar every day. There is talk, furthermore, that in some cases heads and other portions of the body are removed for anatomical examination. The people working at this liquidation job in the institutions are said to be assigned from other areas and are shunned completely by the populace. This personnel is described as frequenting the bars at night and drinking heavily. Quite apart from these overt incidents that exercise the imagination of the people, they are disquieted by the question of whether old folk who have worked hard all their lives and may merely have come into their dotage are also being liquidated. There is talk that the homes for the aged are to be cleaned out too. The people are said to be waiting for legislative regulation providing some orderly method that will insure especially that the aged feeble-minded are not included in the program.

Here one sees what "euthanasia" means in actual practice. According to the records, 275,000 people were put to death in these killing centers. Ghastly as this seems, it should be realized that this program was merely the entering wedge for exterminations of far greater scope in the political program for genocide of conquered nations and the racially unwanted. The methods used and personnel trained in the killing centers for the chronically sick became the nucleus of the much larger centers in the East, where the plan was to kill all Jews and Poles and to cut down the Russian population by 30,000,000.

The original program developed by Nazi hot-heads included also the genocide of the English, with the provision that the English males were to be used as laborers in the vacated territories in the East, there to be worked to death, whereas the English females were to be brought into Germany

to improve the qualities of the German race (This was indeed a peculiar admission on the part of the German eugenicists).

In Germany the exterminations included the mentally defective, psychotics (particularly schizophrenics), epileptics and patients suffering from infirmities of old age and from various organic neurologic disorders such as infantile paralysis, Parkinsonism, multiple sclerosis and brain tumors. The technical arrangements, methods and training of the killer personnel were under the direction of a committee of physicians and other experts headed by Dr. Karl Brandt. The mass killings were first carried out with carbon monoxide gas, but later cyanide gas ("cyclon B") was found to be more effective. The idea of camouflaging the gas chambers as shower baths was developed by Brack, who testified before Judge Sebring that the patients walked in calmly, deposited their towels and stood with their little pieces of soap under the shower outlets, waiting for the water to start running. This statement was ample rebuttal of his claim that only the most severely regressed patients among the mentally sick and only the moribund ones among the physically sick were exterminated. In truth, all those unable to work and considered nonrehabilitable were killed.

All but their squeal was utilized. However, the program grew so big that even scientists who hoped to benefit from the treasure of material supplied by this totalitarian method were disappointed. A neuropathologist, Dr. Hallervorden, who had obtained 500 brains from the killing centers for the insane, gave me a vivid first-hand account.⁵ The Charitable Transport Company for the Sick brought the brains in batches of 150 to 250 at a time. Hallervorden stated:

There was wonderful material among those brains, beautiful mental defectives, malformations and early infantile diseases. I accepted those brains of course. Where they came from and how they came to me was really none of my business.

In addition to the material he wanted, all kinds of other cases were mixed in, such as patients suffering from various types of Parkinsonism, simple depressions, involutional depressions and brain tumors, and all kinds of other illnesses, including psychopathy that had been difficult to handle.

These were selected from the various wards of the institutions according to an excessively simple and quick method. Most institutions did not have enough physicians, and what physicians there were were either too busy or did not care, and they delegated the selection to the nurses and attendants. Whoever looked sick or was otherwise a problem was put on a list and was transported to the killing center. The worst thing about this business was that it produced a certain brutalization of the nursing personnel. They got to simply picking out those whom they did not like, and the doctors had so many patients that they did not even know them, and put their names on the list.

Of the patients thus killed, only the brains were sent to Dr. Hallervorden, they were killed in such

large numbers that autopsies of the bodies were not feasible. That in Dr Hallervorden's opinion, greatly reduced the scientific value of the material. The brains, however, were always well fixed and suspended in formalin exactly according to his instructions. He thinks that the cause of psychiatry was permanently injured by these activities and that psychiatrists have lost the respect of the German people forever. Dr Hallervorden concluded: "Still, there were interesting cases in this material."

In general only previously hospitalized patients were exterminated for reasons of illness. An exception is a program carried out in a northwestern district of Poland, the "Warthegau" where a health survey of the entire population was made by an "SS X-Ray Battalion" headed by Professor Hohlfelder, radiologist of the University of Frankfurt-am-Main. Persons found to be infected with tuberculosis were carted off to special extermination centers.

It is rather significant that the German people were considered by their Nazi leaders more ready to accept the exterminations of the sick than those for political reasons. It was for that reason that the first exterminations of the latter group were carried out under the guise of sickness. So-called "psychiatric experts" were dispatched to survey the inmates of camps with the specific order to pick out members of racial minorities and political offenders from occupied territories and to dispatch them to killing centers with specially made diagnoses such as that of "inveterate German hater" applied to a number of prisoners who had been active in the Czech underground.

Certain classes of patients with mental diseases who were capable of performing labor, particularly members of the armed forces suffering from psychopathy or neurosis, were sent to concentration camps to be worked to death, or to be reassigned to punishment battalions and to be exterminated in the process of removal of mine fields.⁶

A large number of those marked for death for political or racial reasons were made available for "medical" experiments involving the use of involuntary human subjects. From 1942 on, such experiments carried out in concentration camps were openly presented at medical meetings. This program included "terminal human experiments," a term introduced by Dr Rascher to denote an experiment so designed that its successful conclusion depended upon the test person's being put to death.

The Science of Annihilation

A large part of this research was devoted to the science of destroying and preventing life, for which I have proposed the term "ktenology," the science of killing.⁷⁻⁹ In the course of this ktenologic research, methods of mass killing and mass sterilization were investigated and developed for use against non-

German peoples or Germans who were considered useless.

Sterilization methods were widely investigated, but proved impractical in experiments conducted in concentration camps. A rapid method developed for sterilization of females, which could be accomplished in the course of a regular health examination, was the intra-uterine injection of various chemicals. Numerous mixtures were tried, some with iodopine and others containing barium, another was most likely silver nitrate with iodized oil, because the result could be ascertained by x-ray examination. The injections were extremely painful and a number of women died in the course of the experiments. Professor Karl Clauberg reported that he had developed a method at the Auschwitz concentration camp by which he could sterilize 1000 women in one day.

Another method of sterilization, or rather castration, was proposed by Viktor Brack especially for conquered populations. His idea was that x-ray machinery could be built into desks at which the people would have to sit, ostensibly to fill out a questionnaire requiring five minutes, they would be sterilized without being aware of it. This method failed because experiments carried out on 100 male prisoners brought out the fact that severe x-ray burns were produced on all subjects. In the course of this research, which was carried out by Dr Horst Schuman, the testicles of the victims were removed for histologic examination two weeks later. I myself examined 4 castrated survivors of this ghastly experiment. Three had extensive necrosis of the skin near the genitalia, and the other an extensive necrosis of the urethra. Other experiments in sterilization used an extract of the plant *Caladium seguinum*, which had been shown in animal studies by Madaus and his co-workers^{10, 11} to cause selective necrosis of the germinal cells of the testicles as well as the ovary.

The development of methods for rapid and inconspicuous individual execution was the objective of another large part of the ktenologic research. These methods were to be applied to members of the ruling group, including the SS itself, who were suspected of disloyalty. This, of course is an essential requirement in a dictatorship, in which "cut-throat competition" becomes a grim reality and any hint of faintheartedness or lack of enthusiasm for the methods of totalitarian rule is considered a threat to the entire group.

Poisons were the subject of many of these experiments. A research team at the Buchenwald concentration camp, consisting of Drs Joachim Mrugowsky, Erwin Ding-Schuler and Waldemar Hoven, developed the most widely used means of individual execution under the guise of medical treatment — namely, the intravenous injection of phenol or gasoline. Several alkaloids were also investigated, among them aconitine, which was used

by Dr Hoven to kill several imprisoned former fellow SS men who were potential witnesses against the camp commander, Koch, then under investigation by the SS. At the Dachau concentration camp Dr Rascher developed the standard cyanide capsules, which could be easily bitten through, either deliberately or accidentally, if mixed with certain foods, and which, ironically enough, later became the means with which Himmler and Goering killed themselves. In connection with these poison experiments there is an interesting incident of characteristic sociologic significance. When Dr Hoven was under trial by the SS the investigating SS judge, Dr Morgen, proved Hoven's guilt by feeding the poison found in Dr Hoven's possession to a number of Russian prisoners of war, these men died with the same symptoms as the SS men murdered by Dr Hoven. This worthy judge was rather proud of this efficient method of proving Dr Hoven's guilt and appeared entirely unaware of the fact that in the process he had committed murder himself.

Poisons, however, proved too obvious or detectable to be used for the elimination of high-ranking Nazi party personnel who had come into disfavor, or of prominent prisoners whose deaths should appear to stem from natural causes. Phenol or gasoline, for instance, left a telltale odor with the corpse. For this reason a number of more subtle methods were devised. One of these was artificial production of septicemia. An intramuscular injection of 1 cc of pus, containing numerous chains of streptococci, was the first step. The site of injection was usually the inside of the thigh, close to the adductor canal. When an abscess formed it was tapped, and 3 cc of the creamy pus removed was injected intravenously into the patient's opposite arm. If the patient then died from septicemia, the autopsy proved that death was caused by the same organism that had caused the abscess. These experiments were carried out in many concentration camps. At the Dachau camp the subjects were almost exclusively Polish Catholic priests. However, since this method did not always cause death, sometimes resulting merely in a local abscess, it was considered inefficient, and research was continued with other means but along the same lines.

The final triumph of the part of ktenology research aimed at finding a method of inconspicuous execution that would produce autopsy findings indicative of death from natural causes was the development of repeated intravenous injections of suspensions of live tubercle bacilli, which brought on acute military tuberculosis within a few weeks. This method was produced by Professor Dr Heissmeyer, who was one of Dr Gebhardt's associates at the SS hospital of Hohenlychen. As a means of further camouflage, so that the SS at large would not suspect the purpose of these experiments, the preliminary tests for the efficacy of this method

were performed exclusively on children imprisoned in the Neuengamme concentration camp.

For use in "medical" executions of prisoners and of members of the SS and other branches of the German armed forces the use of simple lethal injections, particularly phenol injections, remained the instrument of choice. Whatever methods he used, the physician gradually became the unofficial executioner, for the sake of convenience, informality and relative secrecy. Even on German submarines it was the physician's duty to execute the trouble-makers among the crew by lethal injections.

Medical science has for some time been an instrument of military power in that it preserved the health and fighting efficiency of troops. This essentially defensive purpose is not inconsistent with the ethical principles of medicine. In World War I the German empire had enlisted medical science as an instrument of aggressive military power by putting it to use in the development of gas warfare. It was left to the Nazi dictatorship to make medical science into an instrument of political power—a formidable, essential tool in the complete and effective manipulation of totalitarian control. This should be a warning to all civilized nations, and particularly to individuals who are blinded by the "efficiency" of a totalitarian rule, under whatever name.

This entire body of research as reported so far served the master crime to which the Nazi dictatorship was committed—namely, the genocide of non-German peoples and the elimination by killing, in groups or singly, of Germans who were considered useless or disloyal. In effecting the two parts of this program, Himmler demanded and received the co-operation of physicians and of German medical science. The result was a significant advance in the science of killing, or ktenology.

Medicomilitary Research

Another chapter in Nazi scientific research was that aimed to aid the military forces. Many of these ideas originated with Himmler, who fancied himself a scientist.

When Himmler learned that the cause of death of most SS men on the battlefield was hemorrhage, he instructed Dr Sigmund Rascher to search for a blood coagulant that might be given before the men went into action. Rascher tested this coagulant when it was developed by clocking the number of drops emanating from freshly cut amputation stumps of living and conscious prisoners at the crematorium of Dachau concentration camp and by shooting Russian prisoners of war through the spleen.

Live dissections were a feature of another experimental study designed to show the effects of explosive decompression¹²⁻¹⁴. A mobile decompression chamber was used. It was found that when subjects were made to descend from altitudes of 40,000 to 60,000 feet without oxygen, severe symptoms

of cerebral dysfunction occurred — at first convulsions, then unconsciousness in which the body was hanging limp and later, after waking, temporary blindness, paralysis or severe confusional twilight states. Rascher, who wanted to find out whether these symptoms were due to anoxic changes or to other causes, did what appeared to him the most simple thing: he placed the subjects of the experiment under water and dissected them while the heart was still beating, demonstrating air embolism in the blood vessels of the heart, liver, chest wall and brain.

Another part of Dr Rascher's research, carried out in collaboration with Holzlochner and Finke, concerned shock from exposure to cold.¹⁵ It was known that military personnel generally did not survive immersion in the North Sea for more than sixty to a hundred minutes. Rascher therefore attempted to duplicate these conditions at Dachau concentration camp and used about 300 prisoners in experiments on shock from exposure to cold, of these 80 or 90 were killed. (The figures do not include persons killed during mass experiments on exposure to cold outdoors.) In one report on this work Rascher asked permission to shift these experiments from Dachau to Auschwitz, a larger camp where they might cause less disturbance because the subjects shrieked from pain when their extremities froze white. The results like so many of those obtained in the Nazi research program, are not dependable. In his report Rascher stated that it took from fifty-three to a hundred minutes to kill a human being by immersion in ice water — a time closely in agreement with the known survival period in the North Sea. Inspection of his own experimental records and statements made to me by his close associates showed that it actually took from eighty minutes to five or six hours to kill an undressed person in such a manner, whereas a man in full aviator's dress took six or seven hours to kill. Obviously, Rascher dressed up his findings to forestall criticism, although any scientific man should have known that during actual exposure many other factors, including greater convection of heat due to the motion of water, would affect the time of survival.

Another series of experiments gave results that might have been an important medical contribution if an important lead had not been ignored. The efficacy of various vaccines and drugs against typhus was tested at the Buchenwald and Natzweiler concentration camps. Prevaccinated persons and non-vaccinated controls were injected with live typhus rickettsias, and the death rates of the two series compared. After a certain number of passages, the Matelska strain of typhus rickettsia proved to become avirulent for man. Instead of seizing upon this as a possibility to develop a live vaccine, the experimenters including the chief consultant, Professor Gerhard Rose, who should have known better,

were merely annoyed at the fact that the controls did not die either, discarded this strain and continued testing their relatively ineffective dead vaccines against a new virulent strain. This incident shows that the basic unconscious motivation and attitude has a great influence in determining the scientist's awareness of the phenomena that pass through his vision.

Sometimes human subjects were used for tests that were totally unnecessary, or whose results could have been predicted by simple chemical experiments. For example, 90 gypsies were given unaltered sea water and sea water whose taste was camouflaged as their sole source of fluid, apparently to test the well known fact that such hypertonic saline solutions given as the only source of supply of fluid will cause severe physical disturbance or death within six to twelve days. These persons were subjected to the tortures of the damned, with death resulting in at least 2 cases.

Heteroplastic transplantation experiments were carried out by Professor Dr Karl Gebhardt at Himmler's suggestion. Whole limbs — shoulder, arm or leg — were amputated from live prisoners at Ravensbrueck concentration camp, wrapped in sterile moist dressings and sent by automobile to the SS hospital at Hohenlychen where Professor Gebhardt busied himself with a futile attempt at heteroplastic transplantation. In the meantime the prisoners deprived of a limb were usually killed by lethal injection.

One would not be dealing with German science if one did not run into manifestations of the collector's spirit. By February 1942 it was assumed in German scientific circles that the Jewish race was about to be completely exterminated, and alarm was expressed over the fact that only very few specimens of skulls and skeletons of Jews were at the disposal of science. It was therefore proposed that a collection of 150 body casts and skeletons of Jews be preserved for perusal by future students of anthropology. Dr August Hirt, professor of anatomy at the University of Strassburg, declared himself interested in establishing such a collection at his anatomic institute. He suggested that captured Jewish officers of the Russian armed forces be included, as well as females from Auschwitz concentration camp, that they be brought alive to Natzweiler concentration camp near Strassburg, and that after "their subsequently induced death — care should be taken that the heads not be damaged [sic]" the bodies be turned over to him at the anatomic institute of the University of Strassburg. This was done. The entire collection of bodies and the correspondence pertaining to it fell into the hands of the United States Army.

One of the most revolting experiments was the testing of sulfonamides against gas gangrene by Professor Gebhardt and his collaborators for which young women captured from the Polish Resistance

Movement served as subjects. Necrosis was produced in a muscle of the leg by ligation and the wound was infected with various types of gas-gangrene bacilli, frequently, dirt, pieces of wood and glass splinters were added to the wound. Some of these victims died and others sustained severe mutilating deformities of the leg.

Motivation

An important feature of the experiments performed in concentration camps is the fact that they not only represented a ruthless and callous pursuit of legitimate scientific goals but also were motivated by rather sinister practical ulterior political and personal purposes, arising out of the requirements and problems of the administration of totalitarian rule.

Why did men like Professor Gebhardt lend themselves to such experiments? The reasons are fairly simple and practical, no surprise to anyone familiar with the evidence of fear, hostility, suspicion, rivalry and intrigue, the fratricidal struggle euphemistically termed the "self-selection of leaders," that went on within the ranks of the ruling Nazi party and the SS. The answer was fairly simple and logical. Dr. Gebhardt performed these experiments to clear himself of the suspicion that he had been contributing to the death of SS General Reinhard ("The Hangman") Heydrich, either negligently or deliberately, by failing to treat his wound infection with sulfonamides. After Heydrich died from gas gangrene, Himmler himself told Dr. Gebhardt that the only way in which he could prove that Heydrich's death was "fate determined" was by carrying out a "large-scale experiment" in prisoners, which would prove or disprove that people died from gas gangrene irrespective of whether they were treated with sulfonamides or not.

Dr. Sigmund Rascher did not become the notorious vivisectionist of Dachau concentration camp and the willing tool of Himmler's research interests until he had been forbidden to use the facilities of the Pathological Institute of the University of Munich because he was suspected of having Communist sympathies. Then he was ready to go all out and to do anything merely to regain acceptance by the Nazi party and the SS.

These cases illustrate a method consciously and methodically used in the SS, an age-old method used by criminal gangs everywhere—that of making suspects of disloyalty clear themselves by participation in a crime that would definitely and irrevocably tie them to the organization. In the SS this process of reinforcement of group cohesion was called "Blutkitt" (blood-cement), a term that Hitler himself is said to have obtained from a book on Genghis Khan in which this technic was emphasized.

The important lesson here is that this motivation, with which one is familiar in ordinary crimes, applies also to war crimes and to ideologically conditioned

crimes against humanity—namely, that fear and cowardice, especially fear of punishment or of ostracism by the group, are often more important motives than simple ferocity or aggressiveness.

The Early Change in Medical Attitudes

Whatever proportions these crimes finally assumed, it became evident to all who investigated them that they had started from small beginnings. The beginnings at first were merely a subtle shift in emphasis in the basic attitude of the physicians. It started with the acceptance of the attitude, basic in the euthanasia movement, that there is such a thing as life not worthy to be lived. This attitude in its early stages concerned itself merely with the severely and chronically sick. Gradually the sphere of those to be included in this category was enlarged to encompass the socially unproductive, the ideologically unwanted, the racially unwanted and finally all non-Germans. But it is important to realize that the infinitely small wedged-in lever from which this entire trend of mind received its impetus was the attitude toward the nonrehabitable sick.

It is, therefore, this subtle shift in emphasis of the physicians' attitude that one must thoroughly investigate. It is a recent significant trend in medicine, including psychiatry, to regard prevention as more important than cure. Observation and recognition of early signs and symptoms have become the basis for prevention of further advance of disease.⁸

In looking for these early signs one may well retrace the early steps of propaganda on the part of the Nazis in Germany as well as in the countries that they overran and in which they attempted to gain supporters by means of indoctrination, seduction and propaganda.

The Example of Successful Resistance by the Physicians of the Netherlands

There is no doubt that in Germany itself the first and most effective step of propaganda within the medical profession was the propaganda barrage against the useless, incurably sick described above. Similar, even more subtle efforts were made in some of the occupied countries. It is to the everlasting honor of the medical profession of Holland that they recognized the earliest and most subtle phases of this attempt and rejected it. When Seiss-Inquart, Reich Commissar for the Occupied Netherlands Territories, wanted to draw the Dutch physicians into the orbit of the activities of the German medical profession, he did not tell them "You must send your chronic patients to death factories" or "You must give lethal injections at Government request in your offices," but he couched his order in most careful and superficially acceptable terms. One of the paragraphs in the order of the Reich Commissar of the Netherlands Territories concerning the Netherlands doctors of

19 December 1941 reads as follows "It is the duty of the doctor, through advice and effort, conscientiously and to his best ability, to assist as helper the person entrusted to his care in the maintenance, improvement and re-establishment of his vitality, physical efficiency and health. The accomplishment of this duty is a public task."¹⁶ The physicians of Holland rejected this order unanimously because they saw what it actually meant — namely, the concentration of their efforts on mere rehabilitation of the sick for useful labor, and abolition of medical secrecy. Although on the surface the new order appeared not too grossly unacceptable, the Dutch physicians decided that it is the first, although slight, step away from principle that is the most important one. The Dutch physicians declared that they would not obey this order. When Seiss-Inquart threatened them with revocation of their licenses, they returned their licenses, removed their shingles and, while seeing their own patients secretly, no longer wrote death or birth certificates. Seiss-Inquart retraced his steps and tried to cajole them — still to no effect. Then he arrested 100 Dutch physicians and sent them to concentration camps. The medical profession remained adamant and quietly took care of their widows and orphans, but would not give in. Thus it came about that not a single euthanasia or non-therapeutic sterilization was recommended or participated in by any Dutch physician. They had the foresight to resist before the first step was taken, and they acted unanimously and won out in the end. It is obvious that if the medical profession of a small nation under the conqueror's heel could resist so effectively, the German medical profession could likewise have resisted had they not taken the fatal first step. It is the first seemingly innocent step away from principle that frequently decides a career of crime. Corrosion begins in microscopic proportions.

The Situation in the United States

The question that this fact prompts is whether there are any danger signs that American physicians have also been infected with Hegelian, cold-blooded, utilitarian philosophy and whether early traces of it can be detected in their medical thinking that may make them vulnerable to departures of the type that occurred in Germany. Basic attitudes must be examined dispassionately. The original concept of medicine and nursing was not based on any rational or feasible likelihood that they could actually cure and restore but rather on an essentially maternal or religious idea. The Good Samaritan had no thought of nor did he actually care whether he could restore working capacity. He was merely motivated by the compassion in alleviating suffering. Bernal¹⁷ states that prior to the advent of scientific medicine, the physician's main function was to give hope

to the patient and to relieve his relatives of responsibility. Gradually, in all civilized countries, medicine has moved away from this position, strangely enough in direct proportion to man's actual ability to perform feats that would have been plain miracles in days of old. However, with this increased efficiency based on scientific development went a subtle change in attitude. Physicians have become dangerously close to being mere technicians of rehabilitation. This essentially Hegelian rational attitude has led them to make certain distinctions in the handling of acute and chronic diseases. The patient with the latter carries an obvious stigma as the one less likely to be fully rehabilitable for social usefulness. In an increasingly utilitarian society these patients are being looked down upon with increasing definiteness as unwanted ballast. A certain amount of rather open contempt for the people who cannot be rehabilitated with present knowledge has developed. This is probably due to a good deal of unconscious hostility, because these people for whom there seem to be no effective remedies have become a threat to newly acquired delusions of omnipotence.

Hospitals like to limit themselves to the care of patients who can be fully rehabilitated, and the patient whose full rehabilitation is unlikely finds himself, at least in the best and most advanced centers of healing, as a second-class patient faced with a reluctance on the part of both the visiting and the house staff to suggest and apply therapeutic procedures that are not likely to bring about immediately striking results in terms of recovery. I wish to emphasize that this point of view did not arise primarily within the medical profession, which has always been outstanding in a highly competitive economic society for giving freely and unstintingly of its time and efforts, but was imposed by the shortage of funds available, both private and public. From the attitude of easing patients with chronic diseases away from the doors of the best types of treatment facilities available to the actual dispatching of such patients to killing centers is a long but nevertheless logical step. Resources for the so-called incurable patient have recently become practically unavailable.

There has never in history been a shortage of money for the development and manufacture of weapons of war, there is and should be none now. The disproportion of monetary support for war and that available for healing and care is an anachronism in an era that has been described as the "enlightened age of the common man" by some observers. The comparable cost of jet planes and hospital beds is too obvious for any excuse to be found for a shortage of the latter. I trust that these remarks will not be misunderstood. I believe that armament, including jet planes, are vital for the security of the republic, but adequate maintenance of stand-

Movement served as subjects. Necrosis was produced in a muscle of the leg by ligation and the wound was infected with various types of gas-gangrene bacilli, frequently, dirt, pieces of wood and glass splinters were added to the wound. Some of these victims died, and others sustained severe mutilating deformities of the leg.

Motivation

An important feature of the experiments performed in concentration camps is the fact that they not only represented a ruthless and callous pursuit of legitimate scientific goals but also were motivated by rather sinister practical ulterior political and personal purposes, arising out of the requirements and problems of the administration of totalitarian rule.

Why did men like Professor Gebhardt lend themselves to such experiments? The reasons are fairly simple and practical, no surprise to anyone familiar with the evidence of fear, hostility, suspicion, rivalry and intrigue, the fratricidal struggle euphemistically termed the "self-selection of leaders," that went on within the ranks of the ruling Nazi party and the SS. But it is important to realize that the infinitely small wedged-in lever from which this entire trend of mind received its impetus was the attitude toward the nonrehabilitable sick.

It is, therefore, this subtle shift in emphasis of the physicians' attitude that one must thoroughly investigate. It is a recent significant trend in medicine, including psychiatry, to regard prevention as more important than cure. Observation and recognition of early signs and symptoms have become the basis for prevention of further advance of disease.⁸

In looking for these early signs one may well retrace the early steps of propaganda on the part of the Nazis in Germany as well as in the countries that they overran and in which they attempted to gain supporters by means of indoctrination, seduction and propaganda.

The Example of Successful Resistance by the Physicians of the Netherlands

There is no doubt that in Germany itself the first and most effective step of propaganda within the medical profession was the propaganda barrage against the useless, incurably sick described above. Similar, even more subtle efforts were made in some of the occupied countries. It is to the everlasting honor of the medical profession of Holland that they recognized the earliest and most subtle phases of this attempt and rejected it. When Seiss-Inquart, Reich Commissar for the Occupied Netherlands Territories, wanted to draw the Dutch physicians into the orbit of the activities of the German medical profession, he did not tell them "You must send your chronic patients to death factories" or "You must give lethal injections at Government request in your offices," but he couched his order in most careful and superficially acceptable terms. One of the paragraphs in the order of the Reich Commissar of the Netherlands Territories concerning the Netherlands doctors of

mous" and, most recently the National Multiple Sclerosis Society. All these societies, which are co-ordinated with special medical societies and which received inspiration and guidance from outstanding physicians, are having an extremely wholesome effect in introducing fresh motivating power into the ivory towers of academic medicine. It is indeed interesting and an assertion of democratic vitality that these societies are activated by and for people suffering from illnesses who, under certain dictatorships, would have been slated for euthanasia.

It is thus that these new societies have taken over one of the ancient functions of medicine — namely, to give hope to the patient and to relieve his relatives. These societies need the whole-hearted support of the medical profession. Unfortunately, this support is by no means yet unanimous. A distinguished physician, investigator and teacher at an outstanding university recently told me that he was opposed to these special societies and clinics because they had nothing to offer to the patient. It would be better to wait until someone made a discovery accidentally and then start clinics. It is my opinion, however, that one cannot wait for that. The stimulus supplied by these societies is necessary to give stimulus both to public demand and to academic medicine, which at times grows stale and unproductive even in its most outstanding centers, and whose existence did nothing to prevent the executioner from having logic on his side in Germany.

Another element of this free democratic society and enterprise that has been a stimulus to new developments is the pharmaceutical industry, which, with great vision, has invested considerable effort in the sponsorship of new research.

Dictatorships can be indeed defined as systems in which there is a prevalence of thinking in destructive rather than in ameliorative terms in dealing with social problems. The ease with which destruction of life is advocated for those considered either socially useless or socially disturbing instead of educational or ameliorative measures may be the first danger sign of loss of creative liberty in thinking, which is the hallmark of democratic society. All destructiveness ultimately leads to self-destruction, the fate of the SS and of Nazi Germany is an eloquent example. The destructive principle, once unleashed, is bound to engulf the whole personality and to occupy all its relationships. Destructive urges and destructive concepts arising therefrom cannot remain limited or focused upon one sub-

ject or several subjects alone, but must inevitably spread and be directed against one's entire surrounding world, including one's own group and ultimately the self. The ameliorative point of view maintained in relation to all others is the only real means of self-preservation.

A most important need in this country is for the development of active and alert hospital centers for the treatment of chronic illnesses. They must have active staffs similar to those of the hospitals for acute illnesses, and these hospitals must be fundamentally different from the custodial repositories for derelicts, of which there are too many in existence today. Only thus can one give the right answer to divine scrutiny. Yes, we are our brothers' keepers.

ards of health [and alleviation of suffering are equally vital, both from a practical point of view and from that of morale. All who took part in induction-board examinations during the war realize that the maintenance and development of national health is of as vital importance as the maintenance and development of armament.

The trend of development in the facilities available for the chronically ill outlined above will not necessarily be altered by public or state medicine. With provision of public funds in any setting of public activity the question is bound to come up, "Is it worth while to spend a certain amount of effort to restore a certain type of patient?" This rationalistic point of view has insidiously crept into the motivation of medical effort, supplanting the old Hippocratic point of view. In emergency situations, military or otherwise, such grading of effort may be pardonable. But doctors must beware lest such attitudes creep into the civilian public administration of medicine entirely outside emergency situations, because once such considerations are at all admitted, the more often and the more definitely the question is going to be asked, "Is it worth while to do this or that for this type of patient?" Evidence of the existence of such an attitude stared at me from a report on the activities of a leading public hospital unit, which stated rather proudly that certain treatments were given only when they appeared promising. "Our facilities are such that a case load of 20 patients is regularly carried in selecting cases for treatment careful consideration is given to the prognostic criteria, and in no instance have we instituted treatment merely to satisfy relatives or our own consciences." If only those whose treatment is worth while in terms of prognosis are to be treated, what about the other ones? The doubtful patients are the ones whose recovery appears unlikely, but frequently if treated energetically, they surprise the best prognosticators. And what shall be done during that long time lag after the disease has been called incurable and the time of death and autopsy? It is that period during which it is most difficult to find hospitals and other therapeutic organizations for the welfare and alleviation of suffering of the patient.

Under all forms of dictatorship the dictating bodies or individuals claim that all that is done is being done for the best of the people as a whole, and that for that reason they look at health merely in terms of utility, efficiency and productivity. It is natural in such a setting that eventually Hegel's principle that "what is useful is good" wins out completely. The killing center is the *reductio ad absurdum* of all health planning based only on rational principles and economy and not on humane compassion and divine law. To be sure, American physicians are still far from the point of thinking of killing centers, but they have arrived at a danger point

in thinking, at which likelihood of full rehabilitation is considered a factor that should determine the amount of time, effort and cost to be devoted to a particular type of patient on the part of the social body upon which this decision rests. At this point Americans should remember that the enormity of a euthanasia movement is present in their own midst. To the psychiatrist it is obvious that this represents the eruption of unconscious aggression on the part of certain administrators alluded to above, as well as on the part of relatives who have been understandably frustrated by the tragedy of illness in its close interaction upon their own lives. The hostility of a father erupting against his feeble-minded son is understandable and should be considered from the psychiatric point of view, but it certainly should not influence social thinking. The development of effective analgesics and pain-relieving operations has taken even the last rationalization away from the supporters of euthanasia.

The case, therefore, that I should like to make is that American medicine must realize where it stands in its fundamental premises. There can be no doubt that in a subtle way the Hegelian premise of "what is useful is right" has infected society, including the medical portion. Physicians must return to the older premises, which were the emotional foundation and driving force of an amazingly successful quest to increase powers of healing and which are bound to carry them still farther if they are not held down to earth by the pernicious attitudes of an overdone practical realism.

What occurred in Germany may have been the inexorable historic progression that the Greek historians have described as the law of the fall of civilizations and that Toynbee¹⁸ has convincingly confirmed—namely, that there is a logical sequence from *Koros* to *Hybris* to *Ate*, which means from surfeit to disdainful arrogance to disaster, the surfeit being increased scientific and practical accomplishments, which, however, brought about an inclination to throw away the old motivations and values by disdainful arrogant pride in practical efficiency. Moral and physical disaster is the inevitable consequence.

Fortunately, there are developments in this democratic society that counteract these trends. Notable among them are the societies of patients afflicted with various chronic diseases that have sprung up and are dedicating themselves to guidance and information for their fellow sufferers and for the support and stimulation of medical research. Among the earliest was the mental-hygiene movement, founded by a former patient with mental disease. Then came the National Foundation for Infantile Paralysis, the tuberculosis societies, the American Epilepsy League, the National Association to Control Epilepsy, the American Cancer Society, The American Heart Association, "Alcoholics Anony-

microscopical examination by the pathologist. The first step depends on the physician. He must be able to see the lesion clearly (this often is not easy at the far end of a bronchoscope or sigmoidoscope). On the other hand, since early carcinoma of the cervix may present no visible changes, one must rub the sponge over the area in which these lesions begin, the ring of the external os, the adjacent portion of the lips of the cervix and the adjacent lower cervical canal. When a visible lesion presents a

sections may also be taken. The pathologist can quickly familiarize himself with the findings in sponge biopsy by rubbing sponges over fresh tumors immediately after removal from the patient. Sections from such sponges will show the ease with which cancerous material may be absorbed by a suitable sponge and demonstrated on microscopical examination.

CASE REPORTS

CASE 1 C. J. (8125-48), a 40-year-old married woman, reported to the New York Polyclinic Outpatient Department on May 24, 1948, complaining of backache of 2 years duration.

The patient had 2 children, 13 and 16 years of age. The past history showed pneumonia in 1926. The menstrual periods were regular, occurring every 28 days and lasting for 4 days. No irregularities in menstrual bleeding, no dysmenorrhea and no spotting had been noticed.

Physical examination disclosed a slightly overweight, well developed woman. Examination of the head, neck, chest and abdomen revealed no abnormalities. On pelvic examina-

grayish-white necrotic base, the dead tissue must be removed by gauze before the diagnostic sponge is applied. The success of the method depends more than anything else upon the ability to reach the lesion, and to rub the sponge firmly over it. The technician should embed the sponge so as to cut sections from the flat surface usually discolored after having been rubbed over the ulcer. If tiny particles of tissue are seen in the formalin bottle, they should be processed along with the sponge, and placed in contact with the sponge surface to be cut, before embedding. One may accomplish this by placing the tissue particles in the melted paraffin and then covering them with the sponge. The sections taken from the immediate surface of the paraffin block should be mounted. Deeper

FIGURE 3 Surgical Specimen in Case 1 (Low-Power Photomicrograph of the Cervix)

The plane of the section is perpendicular to the axis of the cervical canal just above the external os. Note the thick layer of darkly staining cells, with finger-like projections into the underlying tissue. Filling, destruction and replacement of mucous glands by the advancing growth are seen.

tion a Bartholin-gland cyst, left side, and a retroverted uterus were found. The cervix uteri on direct visual inspection through a bivalve speculum appeared normal.

The temperature was 99.2°F, the pulse 80, and the respirations 20. The blood pressure was 148/80.

Examination of the blood showed a red-cell count of 4,730,000, with a hemoglobin of 90 per cent (Sahli). The sedimentation rate was 5 mm in 1 hour. The urine was clear, with a negative test for sugar and a faint trace of albumin.

DIAGNOSIS OF EARLY CARCINOMA OF THE CERVIX BY SPONGE BIOPSY*

SIDNEY A. GLADSTONE, M.D.†

NEW YORK CITY

SINCE cancer in its early stage is a localized lesion, successful treatment depends on complete surgical removal of the diseased tissue or its complete destruction by adequate radiation. The diagnosis of cancer by the recognition and proper

its ready accessibility provides an ideal site for the detection of early carcinoma prior to the onset of signs, symptoms or anatomic changes visible on clinical inspection. Two such cases diagnosed by the method of sponge biopsy^{1,2} and treated by hysterectomy are reported below.

METHOD

The method of sponge biopsy depends on the absorption of fluid, cells and tissue particles from the surface of an ulcer or mucous membrane rubbed by an absorbing sponge of suitable structure and chemical composition. The sponge and absorbed contents are fixed in formalin, embedded in paraffin, sectioned by microtome and stained with hematoxylin and eosin. The stained paraffin sections are then examined by a qualified pathologist for the presence of tumor cells and fragments of tumor tissue.

A suitable sponge must be of such chemical composition as to withstand the solvent action of alcohol, chloroform, acetone or other fluids used in tissue preparation. For this purpose we have worked mostly with gelfoam No. 12 (Upjohn). A flat square of sponge 2.0 by 2.0 by 0.5 cm. is clamped along one margin by a surgical sponge forceps. The ulcer is wiped clean with dry sterile gauze, and then the dry diagnostic sponge is rubbed gently over the suspected area. After the sponge becomes wet, it is pressed more firmly between the tissue and the sponge holder, with slight rubbing. Each of the two sponge surfaces is thus brought into contact with the area to be examined, to permit later sectioning from either surface after embedding in paraffin. The flat sponge is used for rubbing of the surface of the cervix uteri, or lesions of the skin, mouth, lower rectum and so forth. When working through a long tube such as a sigmoidoscope, one may employ a small piece of sponge at the end of a uterine forceps. This is also useful for insertion into the external os of the cervix uteri. In bronchoscopy, a special narrow sponge holder is chosen.

To ensure the absorption of an adequate amount of material it is best to rub the sponge around the edge of the ulcer near the surrounding normal tissue. Also, the outside surface of the metal ring of the sponge holder may be filed to produce several radial grooves. These will help to dislodge tiny particles from the ulcer.

The method depends for its success in the first place on the actual transfer of cancerous tissue from the lesion to the sponge, secondly, on the proper preparation of sections and, thirdly, on the recognition of cancerous material in the slide during

FIGURE 1 First Sponge Biopsy in Case 1

interpretation of early clinical signs and symptoms is in several important categories wholly inadequate, as witnessed by the poor results in the treatment of gastric and bronchogenic carcinoma. In lesions of the stomach and lung the symptoms appear and the diagnosis is made at a stage of the disease in which the cancer most often has advanced beyond the possibility of complete removal. For successful treatment in such cases, the detection of the disease will have to be made *before* the onset of clinical complaints. The cervix uteri because of

†Professor of pathology and bacteriology, New York Polyclinic Medical School and Hospital.

About 2 weeks later surgical biopsy in the form of curettings from the external os was done. The pathologist's report was as follows:

The specimen consists of several small fragments of soft red and brown tissue aggregating in all about 0.2 cc. Microscopical examination shows hyperplasia of large undifferentiated epithelial cells in thick layers. The tissue appears coagulated. There is a tendency to concentric formations. Groups of cells that stain more clearly demonstrate large nuclei darkly staining with considerable variation in size and shape. The basement membrane is indistinct and in part is traversed by the growing cells. The diagnosis is epidermoid carcinoma of the cervix.

A month after the cervical os was curetted a complete hysterectomy with bilateral salpingo-oophorectomy was performed. The pathological report was as follows:

The specimen consists of a uterus with both tubes and ovaries attached. The cervix has been incised along the posterior wall. The specimen is fixed in formalin. The uterus measures 9 by 6 by 5 cm. On section the uterine wall measures 2 cm in thickness. The endometrium measures about 3 mm. The lips of the cervix are reddish brown. The surface is somewhat irregular and the external os has a granular appearance. The cervical canal is pale gray. The endometrium is reddish brown. On the lip of the cervix between the os and the circumference in the lower right-hand quadrant there is an ulcerated grayish-brown area 7 mm in diameter. On section the underlying tissue shows the extension of pearly white tissue from the surface, reaching about 5 to 8 mm into the depths. The ovaries feel somewhat firm and measure 2.5 to 3.0 cm in length.

Microscopical examination of the ulcerated area of the cervical lip described in the gross shows an abundant growth of large atypical tumor cells, epidermoid in type, extending in cords and irregular masses into the underlying muscular tissue (Fig. 6). There is considerable necrosis, fibrosis and lymphocytic infiltration between and around the masses of tumor tissue. Surrounding the tumor growth are numerous dilated, thin-walled blood vessels. Between the ulcer and the cervical os the epithelial zone is thickened and made up of large vesicular, anaplastic cells, many containing large nuclei and distinct nucleoli. Irregular masses of invasive tumor tissue are also seen in the area of the external os. The abnormal epithelial growth extends also in the opposite direction over the cervical lip, and at one point makes an abrupt transition to normal epithelium. The latter shows the oblique line often described. In cut sections the hyperplastic surface growth extends down into the mucous glands filling, destroying and replacing them. The individual cells are markedly atypical. The endometrial glands show slight hyperplasia. The myometrium appears normal. In the ovary there are several corpora albicantia and considerable hyperemia. The diagnosis is epidermoid carcinoma of the cervix.

Review of this case indicated that the tissue obtained by surgical biopsy consisted of anaplastic superficial growth. The more differentiated and more characteristic epidermoid type of cancer tissue was confined to the invasive area on the lip. This area was not detectable on clinical inspection. It was missed on surgical biopsy. Sponge biopsy, however, gathered from its surface characteristic cells and tissue particles.

DISCUSSION

Of the 2 cases of cancer of the cervix reported the first was superficial or intraepithelial. The second was similar except that in one area a small invasive tumor mass, 0.8 cm in greatest diameter, had developed. The incidence of early, superficial or intraepithelial cancer of the cervix varies

somewhat according to the specimens or patients studied and the methods used for obtaining material for biopsy. In a study of 1200 whole cervixes, most of which were from patients on whom hysterectomies had been performed, Pund and Auerbach⁴ observed 47 cases of preinvasive carcinoma (almost 4 per cent). TeLinde and Galvin⁵ by the use of surgical biopsy, found 8 early cancers in 704 cases. Foote and Stewart⁶ reported the collection of 27 pathological specimens of intraepithelial carcinoma of the cervix in the Memorial Hospital laboratory.

FIGURE 6 Case 2 Surgical Specimen from Cervix Uteri. A very low-power photomicrograph, showing invasiveness of cancer with destruction of underlying tissue.

during a period of three years. The three reports mentioned demonstrate the frequency of these lesions and indicate the importance of detecting them. Foote and Stewart, by serial sections, demonstrated the precise location of these lesions at the cervical os, cervical canal and cervical lips. These areas are readily accessible to the diagnostic sponge for the collection of tissue for microscopic examination.

SUMMARY

Two cases of early asymptomatic carcinoma of the cervix diagnosed by sponge biopsy are reported. The first case was superficial and intraepithelial. The second was similar but included one invasive area 0.8 cm in greatest diameter. The frequency

Microscopical examination of the sediment demonstrated an occasional white cell and red cell, with no casts. A cervical smear was negative for gonococci.

On October 14 a sponge biopsy was performed by rubbing of a flat piece of sponge over the cervix uteri visualized through the speculum. A longitudinal piece of sponge held at the end of a uterine clamp was inserted into the cervical canal. The sponges were treated and examined in the manner described above. The report of the sponge biopsy was as follows:

Microscopical examination of the sponge from the cervical canal shows clumps of large atypical epithelial tumor cells. A small particle of tissue (Fig 1) is made up of large, darkly staining epithelial cells, with large nuclei, showing marked atypism and variations in size and shape

FIGURE 4 Surgical Specimen in Case 1 (High-Power Photomicrograph)

Cancer is present in the center and to the right, with intact, mucous glands above. The mucous gland below and to the left is partly destroyed by advancing tumor.

The large sponge rubbed over both lips of the cervix and external os shows abundant stratified squamous epithelium, as well as tiny particles of cancer tissue and individual cancer cells.

The sponge biopsy was repeated on October 28, and showed fragments of cancer tissue (Fig 2) in the sponge inserted into the cervical canal. Scattered cancer cells were found in the sponge rubbed over the lips and external os of the cervix.

On the basis of the sponge biopsy, a diagnosis of epidermoid carcinoma of the cervical canal was made, and a total hysterectomy and bilateral salpingo-oophorectomy were performed on November 6.

Pathological examination of the specimens revealed small ovarian cysts, the largest 2 cm in diameter. The tubes measured 8.0 x 0.6 cm and showed several serosal cysts. The uterus appeared normal in shape and measured 10 by 6 by 5 cm. The uterine wall varied from 1.5 to 2.5 cm in thickness. The mucosa of the cervical canal was thickened

near the external os up to about 4.0 mm. A small ulcer, 3 mm in diameter, was seen in this area. On cross section within the thickened mucosa, several pin-point, reddish spots were visible.

Microscopical examination was reported as follows:

There is moderate hyperplasia of the endometrial glands, with dilatation and cyst formation. The mucosa of the cervical canal is covered by a layer of closely packed, darkly staining cells (Fig 3), rather large, showing considerable variation in size and shape. The nuclei are also large and reveal occasional mitotic figures. At several points finger-like projections of this tissue extend into the underlying fibromuscular tissue and into the underlying mucous glands, several of which are partly destroyed and replaced by the invading growth (Fig 4). Also present are several dilated and cystic mucous glands. The epithelial surface covering the external os is intact. Beneath it are several mucous cysts. The diagnosis is epidermoid carcinoma of the cervix in situ.

CASE 1 D S, a 48-year-old woman whose vague complaints were thought to be of menopausal origin, was accordingly referred to a gynecologist for possible endocrine therapy. In the course of pelvic examination a sponge biopsy of the cervix uteri was performed. There were no visible abnormalities of the external os or lips of the cervix on direct inspection.

FIGURE 5 Sponge Biopsy in Case 2

High-power photomicrograph, showing a particle of cancer tissue embedded in the sponge. The cell nuclei are large and darkly staining, with marked variation in size and shape.

There were no abnormalities of menstruation, no abnormal bleeding and no spotting. The findings on sponge biopsy were reported as follows:

Microscopical examination discloses many large, darkly staining, atypical cells, with large nuclei showing marked variations in size and shape. Some cells have double nuclei. Small particles of tissue made up of atypical cells are also present (Fig 5). There is a moderate amount of blood. The findings are those of epidermoid carcinoma of the cervix. Confirmation by surgical biopsy is advisable prior to treatment.

About 2 weeks later surgical biopsy in the form of cuttings from the external os was done. The pathologist's report was as follows:

The specimen consists of several small fragments of soft red and brown tissue aggregating in all about 0.2 cc. Microscopical examination shows hyperplasia of large undifferentiated epithelial cells in thick layers. The tissue appears coagulated. There is a tendency to concentric formations. Groups of cells that stain more clearly demonstrate large nuclei, darkly staining, with considerable variation in size and shape. The basement membrane is indistinct and in part is traversed by the growing cells. The diagnosis is epidermoid carcinoma of the cervix.

A month after the cervical os was curetted a complete hysterectomy with bilateral salpingo-oophorectomy was performed. The pathological report was as follows:

The specimen consists of a uterus with both tubes and ovaries attached. The cervix has been incised along the posterior wall. The specimen is fixed in formalin. The uterus measures 9 by 6 by 5 cm. On section the uterine wall measures 2 cm in thickness. The endometrium measures about 3 mm. The lips of the cervix are reddish brown. DIHYDROSTREPTOMYCIN IN THE TREATMENT OF PULMONARY TUBERCULOSIS*

With Particular Reference to Its Toxicity As Compared with That of Streptomycin

STANTON T ALLISON, M D,† RALPH VOLK, M D,‡ AND GUY R VITAGLIANO, M S§

RUTLAND HEIGHTS, MASSACHUSETTS

SINCE September 1946 the United States Veterans Administration Hospital, Rutland Heights, Massachusetts, a 600-bed hospital for the treatment of veterans with tuberculosis, has been engaged in the study of streptomycin and its effect in controlling various forms of the disease. It is not within the province of this paper to discuss the results of these studies, which have been presented in previous reports.¹⁻⁶ In most cases streptomycin has not been considered to be definitive therapy, but rather a very helpful adjunct to other well established methods of treatment, such as bed rest and the various forms of collapse therapy, in the pulmonary cases, and bed rest alone, or in conjunction with surgical procedures, in the extrapulmonary cases. The latter group includes draining sinuses and tuberculosis of the bones, joints, lymph nodes, alimentary tract, kidneys and peritoneum.

The chief deterrents to the use of streptomycin are toxicity and the rapid emergence of resistant strains of the organism concerned, the *Mycobacterium tuberculosis*. Toxicity for the most part is a neurotoxicity directed against the eighth cranial nerve, particularly its vestibular branch, so that vestibular function is either impaired or lost. Important, but less so than the neurotoxic tendency of the drug, is the allergic reaction, whose chief manifestation is skin eruption. Much of the fear of toxicity has been allayed by shortening of the course of the drug and lessening of the daily dosage. Resistance of the tubercle bacillus to streptomycin is far from remedied and remains the bug-a-boo of the drug's true effectiveness.

To combat the toxicity, Merck and Squibb chemists have been working on various modifications of the original streptomycin with the result that there has emerged a closely related compound produced from crude streptomycin complex by hydrogenation, which has been called dihydrostreptomycin.

We have treated 20 patients with this new compound for ninety days.

The principal object of the study was to determine the toxicity of the drug, although its therapeutic properties have not been overlooked.

Following the *modus operandi* of all streptomycin studies carried out in Veterans Administration Hospitals, more carefully to anticipate and evaluate toxicity from the drug, numerous laboratory tests were carried out before treatment and at weekly intervals thereafter, unless otherwise specified. These procedures consisted of audiograms (done bi-weekly), caloric tests using ice water (done bi-weekly), urine analyses, complete blood counts, erythrocyte sedimentation rates (Cutler method), urea clearance, blood urea nitrogen, prothrombin times, stereoroentgenograms of the chest (monthly) and sputum concentrates for acid-fast bacilli (monthly). In addition to these tests, sensitivity studies were carried out and dihydrostreptomycin blood levels determined.

PREPARATION FOR INJECTION

The drug was received in 1-gm vials, and the material, a white powder, made a colorless clear solution, 4 cc of sterile distilled water was added to the vial, and 2 cc, equivalent to 0.5 gm of the drug, was injected at a dose, usually in the gluteal muscles. In the first few weeks of treatment, injections were given every four hours "around the clock" to the patients receiving 3 gm, and every four hours from 8 a m through 8 p m to those receiving 2 gm daily.

*From the Medical Service, Veterans Administration Hospital, Rutland Heights, Massachusetts. Published with permission of Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or the conclusions drawn by the authors.

†The dihydrostreptomycin used in this study was furnished by Merck and Company, Rahway, New Jersey.

‡Chief, Medical Service, Veterans Administration Hospital.

§Chief of Section, Veterans Administration Hospital.

§Bacteriologist, Veterans Administration Hospital.

The first lots of the drug caused considerable irritating reaction at the site of injection. In addition, there were paresthesias in 6 patients manifested by numbness of the lips. When the study was about half completed, Dr. James Carlisle, medical director of the Merck Company, who had followed our work with interest, sent us some dihydrostreptomycin sulfate for trial, stating that it had been found less irritating in animals than the hydrochloride. We injected 0.5 gm of the sulfate in the left arms of the 20 patients and at the same time injected 0.5 gm of the hydrochloride in the right arms, without informing the patients of our experiment. With one exception all patients had pain, burning or soreness in the right arm and none in the left. The exception had pain in neither arm. We were then convinced that the dihydrostreptomycin hydrochloride was much more irritating than the dihydrostreptomycin sulfate, and since then we have used the sulfate when it was obtainable. Later in the study, injections were given as follows for the patients receiving 3 gm, 0.5 gm in each buttock three times a day, for those receiving 2 gm, 0.5 gm in each buttock twice a day, because injection of 1 gm at one site appeared to be too irritating.

CASES TREATED

Twenty patients with active pulmonary tuberculosis, including 1 with generalized miliary tuberculosis, were treated for ninety days. Half these received 2 gm of dihydrostreptomycin daily, and half 3 gm daily. The extent of the disease was advanced in all cases according to the classification of the National Tuberculosis Association, 18 were far advanced, 1 was moderately advanced, and 1 had generalized miliary tuberculosis. Fourteen patients (70 per cent) had cavity disease, 17 (85 per cent) had bilateral lung involvement, and 6 (30 per cent) had more than 50 per cent exudative disease as determined by roentgenograms. Nineteen patients had positive sputums. We were able to obtain positive cultures in 18 of these. The clinical and roentgenographic indication of a generalized miliary tuberculosis was so profound in 1 patient that treatment was given in spite of negative sputum smears and cultures. Subsequent events in this case confirmed our impression that the hematogenous infection was of tuberculous origin, tuberculous meningitis developed soon after completion of the course, the patient died, and autopsy confirmed the diagnosis. All but 1 of the patients were white men, the exception being a Negro forty-two years of age. The ages ranged from twenty-one to fifty-three, the majority being in the third and fourth decades.

TOXICITY

Subjective Symptoms

During the first week of treatment, aside from the tissue irritation, 6 patients complained of

paresthesias, for the most part involving the lips which were described as "numbness," "feeling of fullness" and "dead sensation" by various patients. One of these patients likewise complained of paresthesias involving the tip of the left thumb, index and middle finger, of forty-eight hours' duration. These paresthesias appeared within the first two days of treatment. They were of short duration in all cases, lasting from five minutes to forty-eight hours. The drug was not discontinued because of them. The paresthesias, having disappeared, did not return. At first it was believed they were manifestations of the neurotoxicity of dihydrostreptomycin. However, since they did not appear in any of the patients who subsequently received other lots of the drug, which presumably had been more purified, it is now believed that these early toxic manifestations were not due to the drug itself but to impurities in the early lots administered.

Two patients complained of gastrointestinal upsets during the course of treatment. 1 of nausea on the morning following institution of treatment, and the other of nausea, vomiting, chills and fever for two days during the third week of treatment. Whether the disturbance was an effect of the drug cannot be stated with certainty, since it may have been caused by a gastrointestinal infection unrelated to treatment.

Between the thirtieth and the forty-seventh day of treatment, 4 patients complained of tinnitus that was of transient duration but recurrent in two patients. This was not accompanied by impairment of hearing or audiometric changes of significant degree in any of the patients, so that the drug was not discontinued because of this symptom. One patient complained of slight dizziness and stated that he walked as though he had "blind staggers." This symptom appeared at the end of the fifth week of treatment. Actually the patient demonstrated little ataxia when he was observed getting out of bed and walking across the room. At that time, caloric tests were normal. On the sixtieth day of treatment, however, ataxia was definite, and the caloric test revealed almost complete loss of vestibular function. This patient received 3 gm of the drug daily. The drug was immediately stopped. No patients demonstrated clinical hypersensitivity to the drug as evidenced by skin eruptions, edema of the eyelids, bronchospasm or arthralgia. There were no cases of agranulocytosis or purpura.

Laboratory Evidence of Toxicity

Six patients (30 per cent) of the group of 20 showed eosinophil counts above 5 per cent. The counts were never higher than 8 per cent and usually appeared in the third and fourth weeks of treatment, returning to normal by the eighth week.

Evidence of renal impairment. Urinalyses were essentially normal in all but 2 cases. One of these patients had a single specimen that showed

many hyaline casts after two weeks of therapy, subsequent specimens were negative. Urine from the other patient showed many white cells and granular casts after four weeks and nine weeks of treatment. This patient's most recent urea clearance has shown a decided drop to 38 per cent, he is fifty-three years of age and has far advanced tuberculosis. Further studies to rule out renal tuberculosis are being performed. Blood urea nitrogen determinations have been normal.

Urea clearance tests showed no significant reduction except in the one case cited above. Blood urea nitrogen determinations were within normal limits in all cases.

There was no clinical evidence of liver damage in any of the patients, although tests of liver function were not carried out, except for a study of weekly prothrombin times in all cases. Prothrombin-time measurements varied through the weeks in most patients, but at no time showed any significantly marked rise or fall from the normal.

Hematologic evidence of toxicity. Red-cell counts were unchanged from pretreatment levels in 11 patients (55 per cent).

Because of the human element of error in counting red blood cells, we considered only deviations of 1,000,000 or more red cells to be significant, 45 per cent showed a drop of 1,000,000 cells after the first week of treatment. All these counts returned to their pretreatment level between the eighth and the twelfth week of treatment.

The photoelectric colorimeter was used for determinations of hemoglobin. Deviations of 5 per cent or more were recorded. Except for 3 patients, who demonstrated a slight fall in hemoglobin soon after treatment started, the determinations in the remaining patients either showed no significant deviation from pretreatment levels or became higher during the early weeks of treatment.

There was considerable variation in the white-cell and differential counts, but in no case was there a definite leukopenia or agranulocytopenia.

Erythrocyte sedimentation rates (Cutler method). Changes of 5 mm. or more from pretreatment readings were recorded. Five patients (25 per cent) demonstrated a fall to normal during the fifth to the tenth week of treatment. Eight (40 per cent) patients demonstrated a fall from pretreatment readings, but not to normal, between the fifth and the twelfth week of treatment. Seven patients demonstrated no change in their sedimentation rates during treatment. Six of these were elevated, and 1 was normal.

Caloric Tests

Bi-weekly caloric tests were carried out, a modified Kobrak technic, injecting 5 cc. of ice water in each ear, being used and the time of appearance of nystagmus and its duration being noted. During the ninety-day course only 1 patient of the

entire group showed any substantial loss in vestibular function.

Audiometric Tests

Bi-weekly audiograms were made on all patients. Only 1 patient revealed any impairment of cochlear-nerve function audiometrically during treatment, and this was slight. There was no clinical deafness.

CLINICAL OBSERVATIONS

In marked contrast to the feeling of well-being and increased appetite, which was striking in the great majority of patients treated with streptomycin, the present group of patients receiving dihydrostreptomycin experienced little benefit in this respect. In fact several patients complained of loss of appetite during the first few weeks of treatment. Euphoria in the group was conspicuous by its absence.

A gain in weight during treatment was observed in 15 patients (75 per cent). The weight of 1 patient remained stationary, and 4 patients (20 per cent) lost 3 pounds or less. Of those who gained, 4, or 20 per cent, showed a gain from 1 to 5 pounds, 3, or 15 per cent, gained from 5 to 10 pounds, and 8, or 40 per cent, gained over 10 pounds.

Seven patients were afebrile at the onset of dihydrostreptomycin therapy, and these patients continued afebrile throughout treatment. Of the 13 patients with fever, 7 reverted to normal, 1 after three days of therapy, 3 after three weeks of therapy, and the remainder in six to twelve weeks.

Eight patients showed pulse rates below 90 before treatment, and these rates did not change. One patient, whose rate ranged between 90 and 100 before treatment, maintained approximately the same slightly elevated rate. Eleven patients had rates persistently above 100 prior to treatment with the drug, 5 of these continued to have rates above 100 but lower than the pretreatment rates, in the other 6 the pulse rates were reduced to 90 or below. (All pulse rates recorded are the patient's usual late afternoon rates taken while he was on complete bed rest.)

Although cough and expectoration were not uniformly severe in this group, all patients showed moderate to marked reduction in the severity of the cough and lessened expectoration.

Nineteen patients had positive sputums prior to the institution of therapy. The twentieth patient was the case of generalized miliary tuberculosis described above. Three patients had sputums that were negative after two weeks to one month of dihydrostreptomycin therapy and were still negative at the completion of their course. In the other 16 the specimens were considered to be positive.

The roentgenograms of the patient with miliary tuberculosis cleared almost completely during treatment, but after completion of his course of therapy,

tuberculous meningitis developed and was confirmed by post-mortem examination

ROENTGENOGRAPHIC OBSERVATIONS

At the completion of the ninety-day course of the drug, 12 patients (60 per cent) showed improvement by x-ray study, however, half these cases showed only slight or minimal improvement. Seven patients (35 per cent) demonstrated no change on x-ray examination, and 1 patient (5 per cent) appeared worse.

Of the 12 patients whose x-ray films revealed improvement, 8 showed improvement after one month, 3 after two months, and 1 at the completion of treatment.

BLOOD LEVELS AND SENSITIVITY STUDIES

Concentration of Dihydrostreptomycin in Blood Serum

Dihydrostreptomycin blood levels were determined by the tube dilution method, *Staphylococcus aureus* (SM) being used as the test organism. Blood-level determinations were carried out on only 6 patients. A single determination was done on each patient. Blood for the tests was drawn within an hour of the administration of dihydrostreptomycin. At the time these tests were carried out, patients were being given single intramuscular injections of 1 gm twice daily, or three times daily, depending upon the regimen followed for their particular group.

The average one-hour blood level for a group of 3 patients receiving 3 gm of dihydrostreptomycin daily (three divided doses of 1 gm each) was found to be 42.6 microgm per cubic centimeter. The average one-hour blood level for a group of 3 patients receiving 2 gm of dihydrostreptomycin daily (two divided doses of 1 gm each) was found to be 20.7 microgm per cubic centimeter.

Determination of Dihydrostreptomycin Sensitivity of Tubercle Bacilli

Routine sensitivity determinations were performed with the use of a Dubos liquid medium containing varying concentrations of dihydrostreptomycin. Tubes with dihydrostreptomycin, as well as suitable controls, were inoculated with standard suspensions of five-day-old cultures of tubercle bacilli in a Dubos medium prepared from primary cultures grown on potato-egg-glycerin slants. Inoculated tubes were incubated at 37°C. Development of turbidity, indicating active growth of the tubercle bacilli, often could be noted within one or two days. A Coleman model 6 junior clinical spectrophotometer, measuring transmission of light at a wave length of 620 millimicrons, was used in these determinations. Final readings were not made before the fourteenth day of incubation, however.

To supplement the routine procedure described above, sensitivity determinations on recent speci-

mens have been carried out with a modified Herrold egg-yolk-agar solid medium with malachite green⁷ containing varying concentrations of dihydrostreptomycin. Utilization of this medium permits results of sensitivity determinations to be placed on a quantitative, as well as a qualitative, basis, since the ratio of resistant to sensitive tubercle bacilli in a given inoculum can be estimated readily by comparison of the amounts of growth in test cultures with that of the control culture.

Complete data on sensitivity tests for all twenty patients in this series are not available, since cultural studies on recently submitted specimens are still in progress.

As was expected, pretreatment cultures of tubercle bacilli obtained from 18 of the 20 patients were found to be sensitive to 1 microgm per cubic centimeter of dihydrostreptomycin. It has not been found possible thus far to demonstrate tubercle bacilli by cultural methods in sputum specimens obtained from the other 2 patients, 1 of whom was being included in the group that received 3 gm of dihydrostreptomycin daily, and the other in the group that received 2 gm daily.

Sufficient data have been accumulated to show that 4 patients of the 10 who received 3 gm of dihydrostreptomycin daily produced tubercle bacilli resistant to 100 (or more) microgm per cubic centimeter of dihydrostreptomycin within the first thirty to fifty days of therapy. One patient of the 10 who received 2 gm daily also demonstrated resistant tubercle bacilli. This was noted on the ninety-fourth day following institution of therapy and represented cultural data obtained from a post-treatment specimen. It is not possible to estimate more closely at what time resistance to dihydrostreptomycin developed since, inadvertently, no other specimens were submitted to the laboratory prior to the end of therapy.

By use of the modified Herrold medium, it was found that in each case in which resistance to dihydrostreptomycin had developed, 75 to 100 per cent of the culturally recoverable tubercle bacilli present in corresponding sputum specimens were resistant to at least 100 microgm per cubic centimeter of dihydrostreptomycin.

The sputum of a patient who received 3 gm of dihydrostreptomycin daily was positive by culture six weeks after termination of therapy. The culture proved sensitive to less than 1 microgm per cubic centimeter of dihydrostreptomycin. Incomplete studies on 2 other patients of this series show that 1 patient's culture was sensitive at the thirty-eighth day, and the other on the seventy-second day of treatment. Incomplete studies on 4 patients who received 2 gm daily show that cultures were still sensitive at the end of eighty-five, eighty-three, sixty-three and fifty-three days of treatment, respectively. No post-treatment data for this group are available.

many hyaline casts after two weeks of therapy, subsequent specimens were negative. Urine from the other patient showed many white cells and granular casts after four weeks and nine weeks of treatment. This patient's most recent urea clearance has shown a decided drop to 38 per cent, he is fifty-three years of age and has far advanced tuberculosis. Further studies to rule out renal tuberculosis are being performed. Blood urea nitrogen determinations have been normal.

Urea clearance tests showed no significant reduction except in the one case cited above. Blood urea nitrogen determinations were within normal limits in all cases.

There was no clinical evidence of liver damage in any of the patients, although tests of liver function were not carried out, except for a study of weekly prothrombin times in all cases. Prothrombin-time measurements varied through the weeks in most patients, but at no time showed any significantly marked rise or fall from the normal.

Hematologic evidence of toxicity. Red-cell counts were unchanged from pretreatment levels in 11 patients (55 per cent).

Because of the human element of error in counting red blood cells, we considered only deviations of 1,000,000 or more red cells to be significant, 45 per cent showed a drop of 1,000,000 cells after the first week of treatment. All these counts returned to their pretreatment level between the eighth and the twelfth week of treatment.

The photoelectric colorimeter was used for determinations of hemoglobin. Deviations of 5 per cent or more were recorded. Except for 3 patients, who demonstrated a slight fall in hemoglobin soon after treatment started, the determinations in the remaining patients either showed no significant deviation from pretreatment levels or became higher during the early weeks of treatment.

There was considerable variation in the white-cell and differential counts, but in no case was there a definite leukopenia or agranulocytopenia.

Erythrocyte sedimentation rates (Cutler method). Changes of 5 mm or more from pretreatment readings were recorded. Five patients (25 per cent) demonstrated a fall to normal during the fifth to the tenth week of treatment. Eight (40 per cent) patients demonstrated a fall from pretreatment readings, but not to normal, between the fifth and the twelfth week of treatment. Seven patients demonstrated no change in their sedimentation rates during treatment. Six of these were elevated, and 1 was normal.

Caloric Tests

Bi-weekly caloric tests were carried out, a modified Kobrak technic, injecting 5 cc of ice water in each ear, being used and the time of appearance of nystagmus and its duration being noted. During the ninety-day course only 1 patient of the

entire group showed any substantial loss in vestibular function.

Audiometric Tests

Bi-weekly audiograms were made on all patients. Only 1 patient revealed any impairment of cochlear-nerve function audiometrically during treatment, and this was slight. There was no clinical deafness.

CLINICAL OBSERVATIONS

In marked contrast to the feeling of well-being and increased appetite, which was striking in the great majority of patients treated with streptomycin, the present group of patients receiving dihydrostreptomycin experienced little benefit in this respect. In fact several patients complained of loss of appetite during the first few weeks of treatment. Euphoria in the group was conspicuous by its absence.

A gain in weight during treatment was observed in 15 patients (75 per cent). The weight of 1 patient remained stationary, and 4 patients (20 per cent) lost 3 pounds or less. Of those who gained, 4, or 20 per cent, showed a gain from 1 to 5 pounds, 3, or 15 per cent, gained from 5 to 10 pounds, and 8, or 40 per cent, gained over 10 pounds.

Seven patients were afebrile at the onset of dihydrostreptomycin therapy, and these patients continued afebrile throughout treatment. Of the 13 patients with fever, 7 reverted to normal, 1 after three days of therapy, 3 after three weeks of therapy, and the remainder in six to twelve weeks.

Eight patients showed pulse rates below 90 before treatment, and these rates did not change. One patient, whose rate ranged between 90 and 100 before treatment, maintained approximately the same slightly elevated rate. Eleven patients had rates persistently above 100 prior to treatment with the drug, 5 of these continued to have rates above 100 but lower than the pretreatment rates, in the other 6 the pulse rates were reduced to 90 or below. (All pulse rates recorded are the patient's usual late afternoon rates taken while he was on complete bed rest.)

Although cough and expectoration were not uniformly severe in this group, all patients showed moderate to marked reduction in the severity of the cough and lessened expectoration.

Nineteen patients had positive sputums prior to the institution of therapy. The twentieth patient was the case of generalized miliary tuberculosis described above. Three patients had sputums that were negative after two weeks to one month of dihydrostreptomycin therapy and were still negative at the completion of their course. In the other 16 the specimens were considered to be positive.

The roentgenograms of the patient with miliary tuberculosis cleared almost completely during treatment, but after completion of his course of therapy,

tuberculous meningitis developed and was confirmed by post-mortem examination

ROENTGENOGRAPHIC OBSERVATIONS

At the completion of the ninety-day course of the drug, 12 patients (60 per cent) showed improvement by x-ray study, however, half these cases showed only slight or minimal improvement. Seven patients (35 per cent) demonstrated no change on x-ray examination, and 1 patient (5 per cent) appeared worse.

Of the 12 patients whose x-ray films revealed improvement, 8 showed improvement after one month, 3 after two months, and 1 at the completion of treatment.

BLOOD LEVELS AND SENSITIVITY STUDIES

Concentration of Dihydrostreptomycin in Blood Serum

Dihydrostreptomycin blood levels were determined by the tube dilution method, *Staphylococcus aureus* (SM) being used as the test organism. Blood-level determinations were carried out on only 6 patients. A single determination was done on each patient. Blood for the tests was drawn within an hour of the administration of dihydrostreptomycin. At the time these tests were carried out, patients were being given single intramuscular injections of 1 gm twice daily, or three times daily, depending upon the regimen followed for their particular group.

The average one-hour blood level for a group of 3 patients receiving 3 gm of dihydrostreptomycin daily (three divided doses of 1 gm each) was found to be 42.6 microgm per cubic centimeter. The average one-hour blood level for a group of 3 patients receiving 2 gm of dihydrostreptomycin daily (two divided doses of 1 gm each) was found to be 20.7 microgm per cubic centimeter.

Determination of Dihydrostreptomycin Sensitivity of Tubercle Bacilli

Routine sensitivity determinations were performed with the use of a Dubos liquid medium containing varying concentrations of dihydrostreptomycin. Tubes with dihydrostreptomycin, as well as suitable controls, were inoculated with standard suspensions of five-day-old cultures of tubercle bacilli in a Dubos medium prepared from primary cultures grown on potato-egg-glycerin slants. Inoculated tubes were incubated at 37°C. Development of turbidity, indicating active growth of the tubercle bacilli, often could be noted within one or two days. A Coleman model 6 junior clinical spectrophotometer measuring transmission of light at a wave length of 620 millimicrons, was used in these determinations. Final readings were not made before the fourteenth day of incubation, however.

To supplement the routine procedure described above, sensitivity determinations on recent speci-

mens have been carried out with a modified Herrold egg-volk-agar solid medium with malachite green⁷ containing varying concentrations of dihydrostreptomycin. Utilization of this medium permits results of sensitivity determinations to be placed on a quantitative, as well as a qualitative, basis, since the ratio of resistant to sensitive tubercle bacilli in a given inoculum can be estimated readily by comparison of the amounts of growth in test cultures with that of the control culture.

Complete data on sensitivity tests for all twenty patients in this series are not available, since cultural studies on recently submitted specimens are still in progress.

As was expected, pretreatment cultures of tubercle bacilli obtained from 18 of the 20 patients were found to be sensitive to 1 microgm per cubic centimeter of dihydrostreptomycin. It has not been found possible thus far to demonstrate tubercle bacilli by cultural methods in sputum specimens obtained from the other 2 patients, 1 of whom was being included in the group that received 3 gm of dihydrostreptomycin daily, and the other in the group that received 2 gm daily.

Sufficient data have been accumulated to show that 4 patients of the 10 who received 3 gm of dihydrostreptomycin daily produced tubercle bacilli resistant to 100 (or more) microgm per cubic centimeter of dihydrostreptomycin within the first thirty to fifty days of therapy. One patient of the 10 who received 2 gm daily also demonstrated resistant tubercle bacilli. This was noted on the ninety-fourth day following institution of therapy and represented cultural data obtained from a post-treatment specimen. It is not possible to estimate more closely at what time resistance to dihydrostreptomycin developed since, inadvertently, no other specimens were submitted to the laboratory prior to the end of therapy.

By use of the modified Herrold medium, it was found that in each case in which resistance to dihydrostreptomycin had developed, 75 to 100 per cent of the culturally recoverable tubercle bacilli present in corresponding sputum specimens were resistant to at least 100 microgm per cubic centimeter of dihydrostreptomycin.

The sputum of a patient who received 3 gm of dihydrostreptomycin daily was positive by culture six weeks after termination of therapy. The culture proved sensitive to less than 1 microgm per cubic centimeter of dihydrostreptomycin. Incomplete studies on 2 other patients of this series show that 1 patient's culture was sensitive at the thirty-eighth day, and the other on the seventy-second day of treatment. Incomplete studies on 4 patients who received 2 gm daily show that cultures were still sensitive at the end of eighty-five, eighty-three, sixty-three and fifty-three days of treatment, respectively. No post-treatment data for this group are available.

Supported by the data presented above there appears to be a trend showing that the resistance to dihydrostreptomycin develops in direct proportion to the size of the dosage used in therapy.

Though no final conclusions can be reached on the basis of the foregoing partially complete studies, it seems probable that the regimen consisting of intramuscular administration of 3 gm of dihydrostreptomycin daily for a period of ninety days will result in a higher percentage of cases resistant to dihydrostreptomycin than a similar regimen of 2 gm daily.

DISCUSSION

Nineteen patients with pulmonary tuberculosis and 1 with generalized miliary tuberculosis have been treated with dihydrostreptomycin. Ten patients received 2 gm of the drug daily, and 10 received 3 gm daily, for a period of ninety days. It was the main purpose of our study to evaluate any toxicity that the drug might possess in the dosage given. Accordingly, numerous laboratory tests were carried out at regular intervals, for the most part at weekly intervals. We also evaluated subjective symptoms and signs indicative of toxicity. The early symptoms of paresthesias in 6 patients, at first thought to be evidences of neurotoxicity of the drug, now appear to be evidences of impurities in the first lots of drug administered, since subsequent lots failed to produce these symptoms. Tinnitus, which developed in 4 patients, may well have been a true neurotoxic manifestation, since this symptom appeared later in the course of treatment. Audiometric observations were little changed from pretreatment readings. The nausea reported in 2 patients was an early symptom and may or may not have been significant. It does not appear to be a characteristic toxic manifestation of either dihydrostreptomycin or streptomycin. Since 1 patient receiving 3 gm daily practically lost vestibular function, and had to be dropped from the course on the sixtieth day, this demonstrates the possibility of specific toxic effects on the vestibular nerve.

Compared with streptomycin in similar dosage, vestibular-nerve toxicity appears considerably less in this group receiving dihydrostreptomycin. In our previous studies with streptomycin, of our original group of 20 patients receiving 1.8 gm for a hundred and twenty days, 75 per cent lost vestibular function by the end of the course, and most of these had lost function by the end of sixty days. In our

subsequent group of 31 patients who received 2 gm of streptomycin for sixty days, 64 per cent completely lost vestibular function.

Eosinophilia, which was common in our series of patients receiving various dosages of streptomycin, occurred with much less frequency in the present group of dihydrostreptomycin-treated patients. For example, 30 per cent of the latter showed eosinophil counts from 5 to 8 per cent, whereas 75 per cent of the former had counts that reached an upper limit of 17 per cent. This is consistent with the lessened toxicity observed in the present study.

Renal damage has not been observed in our study, and no evidence of renal irritation has been noted except in 1 case, in contrast to 40 to 50 per cent who received 1.8 gm of streptomycin and showed frequent albuminuria and cylindruria—not in themselves evidences of renal damage but certainly of probable renal irritation.

There has been no lasting effect of the drug on the hematopoietic system.

Prothrombin times were not altered significantly during treatment. No other liver-function tests were done, but no patient appeared to develop clinical evidence of liver damage.

Improvement was manifested by weight gain, lessened cough and expectoration, and disappearance of fever in all patients.

True evaluation of conversion of sputum cannot be made in this series since the time of observation is too short. At least three months of negative sputum should be required before one can consider a conversion definite.

Erythrocyte sedimentation rates were significantly lowered in 65 per cent of the group during treatment. This incidence is scarcely different from the decreases in the sedimentation rates that occurred in 75 per cent of 20 patients who received 1.8 gm streptomycin for a hundred and twenty days.

Roentgenographic improvement was observed in 60 per cent, and half of these patients showed only slight or minimal improvement. This is in contrast with the first group receiving 1.8 gm of streptomycin for a hundred and twenty days, who showed roentgenographic improvement at the end of ninety days of treatment in 75 per cent. In a series of 31 patients receiving 2 gm of streptomycin for sixty days, 90 per cent showed improvement. In a group of 13 patients receiving 1 gm of streptomycin for a hundred and twenty days, 84 per cent showed improvement by roentgenograms.

Therefore, not only the incidence of improvement but also the degree of improvement in the individual cases appeared less with dihydrostreptomycin.

CONCLUSIONS

From the observations in this group of 20 patients treated with intramuscular injections of 2 and 3 gm of dihydrostreptomycin daily for ninety days it is concluded that, in this dosage, the drug is less toxic than streptomycin in similar dosage.

The 2 patients showing the more serious evidences of toxicity, loss of vestibular function in 1 and renal irritation in the other, received 3 gm of the drug daily.

Our observations indicate that dihydrostreptomycin in the dosage given may be less effective therapeutically than streptomycin given in similar or smaller dosage.

Resistance studies are completed and available on only 12 patients in the group at this writing, 5 of whom developed resistant organisms during treatment.

Addendum—Because of the development of cochlear-nerve damage in 4 of the 20 cases reported subsequent to completion of the course of therapy, a brief description of the development of symptoms is important.

Follow-up study on the patient with ataxia on the sixtieth day of treatment, described above reveals that he has no residual dizziness or ataxia but vestibular function as interpreted by the caloric test has not returned. One week after discontinuation of therapy tinnitus developed and this has become slowly more marked. This patient's audiogram was not quite so good after sixty days of therapy as it was before treatment, and it has become slightly worse though progressively so, for five months.

The second patient, a fifty-two-year-old man received 2.0 gm of dihydrostreptomycin daily for ninety days. One month after completion of his course of treatment he complained of moderate tinnitus which has remained unchanged to the present (three months after treatment). Concomitantly he complained of occasional staggering and loss of balance when bending over, these symptoms being exaggerated in the dark. No deafness was noted, but at the onset of tinnitus slight impairment of hearing was shown by the audiogram.

The third patient, a thirty-year-old man, received 3.0 gm of dihydrostreptomycin daily for a period of ninety days.

There was no evidence of cochlear-nerve involvement until two months after treatment, and since then he has had occasional tinnitus and some clinical impairment of hearing. His audiogram also showed some impairment of function at the time tinnitus developed.

The fourth patient, a thirty-seven-year-old man, received 3.0 gm of dihydrostreptomycin daily for ninety days. One month after treatment marked tinnitus and mild deafness developed, both of which increased markedly in severity for the following month. An audiogram taken at the onset of tinnitus showed impairment of function. The audiogram taken a month later showed increased impairment.

In addition to these cases a patient came to us after receiving dihydrostreptomycin for about two months in another hospital. Because he had miliary disease, we decided to continue antibiotic therapy but changed to 2.0 gm of streptomycin daily. About a month after admission to this hospital (a month after dihydrostreptomycin had been stopped), he began to complain of deafness, and during the next month he became almost totally deaf.

We must add therefore to our discussion and conclusions, that in this admittedly small series of 20 cases, 4, or 20 per cent suffered cochlear-nerve damage, which became apparent only after dihydrostreptomycin therapy was completed. In 3 of these cases nerve damage was not apparent until at least a month after completion of treatment.

Though streptomycin is a definite toxin to the eighth nerve it more specifically attacks the vestibular branch, and much less often the cochlear division. Dihydrostreptomycin, on the other hand, appears to attack the cochlear division as frequently as the vestibular division of the eighth nerve, and much more often than streptomycin does.

We therefore believe that dihydrostreptomycin, in the dosage used at this hospital, is not the innocuous drug that we hoped it would be.

FRACTURES OF THE DISTAL END OF THE RADIUS COMPLICATED BY FRACTURES OF THE CARPAL SCAPHOID

O D CHRISMAN, M D,* AND J H SHORTELL, M D †

BALTIMORE, MARYLAND, AND BOSTON, MASSACHUSETTS

THERE is a teaching that a fall on the outstretched hand may cause either a Colles fracture or a fractured carpal scaphoid, the latter usually occurring in young adults and the former in older people^{1,2}. Most of the literature ignores the possibility of both simultaneously. Our recent experience shows that the combination of the two fractures is a difficult problem that occurs in a significant number of cases and through a wide age range. Scudder,³ Brittain,⁴ Kev,⁵ Cleveland⁶ and other authors have stated that fractures of the distal end of the radius and of the carpal scaphoid can occur simultaneously at the same injury. Most of these authorities have considered the combination rare, and none discuss its frequency or its treatment. The mechanism of both injuries is nearly always the same — a fall on the outstretched hand. Force against the scaphoid and radius is indirectly applied either through the first metacarpal and the greater multangular,⁶ or through the second and third metacarpals and the capitate.² These bones may also be simultaneously fractured.^{6,7} Dickinson and Shannon,⁸ reporting 257 scaphoid fractures in soldiers whose average age was twenty-eight years, found 3 associated fractures of the radial styloid and 2 fractures of the shaft of the radius (the level of the fracture unspecified). Kellam and McGoe,⁹ reporting from a Canadian Army hospital, found that of 331 successive fractures of the radius and ulna, at all levels, 7 per cent of patients had carpal injuries, and that 10 per cent with injuries of the distal third of the radius had coincidental lesions of the carpus. No breakdown as to the specific carpal bone or the type of radial fracture is available, but in all probability the majority of the carpal injuries were fractures of the scaphoid.

An analysis of our wrist fractures for about six months shows that the combination is not uncommon, and that difficult problems of both diagnosis and treatment are met.

ANALYSIS OF CASES

Three hundred consecutive cases of recent fracture of the distal 5 cm of the radius of all types were studied. These cases were seen between September, 1946, and April, 1947. Twenty of the 300 patients, or 6.6 per cent, had associated fractures of the carpus. Of these, 15, or 5 per cent, had fractures of the body (either waist or proximal

pole) of the scaphoid, 2 had fractures of the triquetrum, and there were 1 each of the lunate, capitate and greater multangular.

The combination of radial and scaphoid fractures occurred over a wide age range. The youngest patient was fifteen, and the oldest, seventy-nine. The average age was forty-four and seven-tenths years. More than half the cases were in males. Ten of the 15 patients had radial fractures of the Colles type. 1 was impacted without displacement, 5 had backward tilting of the distal fragment, and 4 had comminuted "T" fractures involving the joint. Of the remaining 5, 3 had a chauffeur fracture of the radial styloid, 1 had a Barton fracture of the dorsal articulating surface, and there was 1 epiphyseal fracture with wide displacement of the distal epiphysis and a dorsal metaphyseal fragment. All these cases resulted from a fall on the outstretched hand except for the fractures of the radial styloid, which occurred from blows forcing the hand into dorsal and radial flexion. One case, similar to that of Cleveland,⁶ had associated fractures of the greater multangular, the scaphoid and the radius (Colles type). Another case (Fig 1) illustrates a different line of force, with fractures of the base of the third metacarpal, the waist of the scaphoid and a comminuted Colles fracture involving the joint. This case required four and a half months of immobilization for bony union to occur in the scaphoid.

DIAGNOSTIC PROBLEM

It is hard enough to diagnose a fracture of the scaphoid when the radius is not broken. A case with separation of the scaphoid fragments presents no diagnostic difficulty, but the barely visible hairline, which may not develop until many days after injury, is a more serious problem. The pain and swelling of the radial fracture mask the signs and symptoms referable to the scaphoid, and the surgeon is apt to see at a glance the gross deformity of the radius without bothering to look farther for a suspicious hairline in the scaphoid. It is very easy to concentrate attention on the radius to the exclusion of the carpus in check x-ray films, in which oblique views are seldom required. A policy of taking frequent careful scaphoid series is the only program that can prevent most errors.^{2,6,8}

THERAPEUTIC PROBLEM

None of the authors who discuss the occurrence of fractures of the scaphoid complicated by a comminuted Colles fracture mention the paradox of

*Resident surgeon Johns Hopkins Hospital formerly fellow Orthopedic Service Boston City Hospital

†Surgeon-in-chief Orthopedic Service Boston City Hospital

treatment that confronts the surgeon. Dorsiflexion with radial deviation is commonly accepted for treatment of the fractured scaphoid^{2 5 10 12} but ulnar deviation with volar flexion of the wrist is generally required for treatment of the Colles fracture with a tendency to slip after reduction. Any attempt to compromise may be unfortunate, non-union of the scaphoid and malunion of the radius being equally undesirable. Fortunately, this dilemma is not always encountered. A chauffeur fracture associated with scaphoid fractures may be treated for the scaphoid alone, especially since dorsal and radial flexion of the wrist relaxes the brachioradialis pull, preventing displacement of the radial styloid. Some Colles fractures and nearly all epiphyseal fractures of the distal radius are stable after reduction and can be immobilized in slight cockup or neutral position with radial deviation. They should, however, be followed very carefully to prevent or treat a change in position. When a cockup plaster gauntlet was used from the start in 5 favorable cases, healing took place within five to eight weeks. The method of Soto-Hall^{10 11} was used for fixation, except that the distal joint of the thumb was left free.

Most displaced Colles fractures cannot be held in dorsiflexion, however, and we have immobilized these in volar and ulnar flexion, changing the position to 20 to 30° of cockup in three or four weeks. This is very similar to the treatment of the scaphoid fracture associated with luxation of the lunate, since the lunate may also dislocate in a position of dorsiflexion.¹¹ Speed¹³ and Cravener and McElroy¹⁴ treated scaphoid fractures successfully in volar and radial flexion, although they do not recommend it now. We have treated the radius first because it heals first, with the important addition that the proximal phalanx of the thumb was included in the cast to prevent motion of the scaphoid fragments. This is easily done with a small amount of plaster, and prevents local resorption and cystic changes, which otherwise occur in a cast for the Colles fractures if the scaphoid fracture is not suspected. Six cases so treated have required nine to twenty weeks of immobilization for union to occur, and have needed extensive physiotherapy thereafter.

In 2 elderly patients of the series, in whom marked osteoporosis and vascular changes developed, active motion and physiotherapy were considered to be more important to the functional result than immobilization until bony union eventuated. Accordingly, after five or six weeks, casts were omitted and physiotherapy begun. We lost track of 2 other cases. Unfortunately, the follow-up study on all cases is not complete enough to warrant final conclusions of the best method of treatment.

SUMMARY AND CONCLUSIONS

Three hundred consecutive, recent fractures of the distal radius were complicated by fracture of the carpal scaphoid in 15 cases (5 per cent). The combination cannot be considered a rarity.

Diagnosis of the scaphoid fracture is difficult in presence of a radial fracture that dominates the x-ray picture and masks symptoms due to the fractured scaphoid.

Treatment of the combination presents a difficult paradox concerning position of immobilization. When possible, we have treated such injuries as

FIGURE 1. Fractures of the Base of the Third Metacarpal and the Waist of the Scaphoid, with a Comminuted Colles Fracture of the Joint.

though they were uncomplicated scaphoid fractures, when that could not be done, we have used volar and ulnar flexion of the wrist with inclusion of the proximal phalanx of the thumb in the cast to prevent motion of the scaphoid fragments. The position was changed to cockup in four weeks when there was no danger of displacing the radial fragments.

FRACTURES OF THE DISTAL END OF THE RADIUS COMPLICATED BY FRACTURES OF THE CARPAL SCAPHOID

O D CHRISMAN, M D,* AND J H SHORTELL, M D †

BALTIMORE, MARYLAND, AND BOSTON, MASSACHUSETTS

THERE is a teaching that a fall on the outstretched hand may cause either a Colles fracture or a fractured carpal scaphoid, the latter usually occurring in young adults and the former in older people.^{1, 2} Most of the literature ignores the possibility of both simultaneously. Our recent experience shows that the combination of the two fractures is a difficult problem that occurs in a significant number of cases and through a wide age range. Scudder,³ Brittain,⁴ Key,⁵ Cleveland⁶ and other authors have stated that fractures of the distal end of the radius and of the carpal scaphoid can occur simultaneously at the same injury. Most of these authorities have considered the combination rare, and none discuss its frequency or its treatment. The mechanism of both injuries is nearly always the same — a fall on the outstretched hand. Force against the scaphoid and radius is indirectly applied either through the first metacarpal and the greater multangular,⁶ or through the second and third metacarpals and the capitate.² These bones may also be simultaneously fractured.^{6, 7} Dickinson and Shannon,⁸ reporting 257 scaphoid fractures in soldiers whose average age was twenty-eight years, found 3 associated fractures of the radial styloid and 2 fractures of the shaft of the radius (the level of the fracture unspecified). Kellam and McGoev,⁹ reporting from a Canadian Army hospital, found that of 331 successive fractures of the radius and ulna, at all levels, 7 per cent of patients had carpal injuries, and that 10 per cent with injuries of the distal third of the radius had coincidental lesions of the carpus. No breakdown as to the specific carpal bone or the type of radial fracture is available, but in all probability the majority of the carpal injuries were fractures of the scaphoid.

An analysis of our wrist fractures for about six months shows that the combination is not uncommon, and that difficult problems of both diagnosis and treatment are met.

ANALYSIS OF CASES

Three hundred consecutive cases of recent fracture of the distal 5 cm of the radius of all types were studied. These cases were seen between September, 1946, and April, 1947. Twenty of the 300 patients, or 6.6 per cent, had associated fractures of the carpus. Of these, 15, or 5 per cent, had fractures of the body (either waist or proximal

pole) of the scaphoid, 2 had fractures of the triquetrum, and there were 1 each of the lunate, capitate and greater multangular.

The combination of radial and scaphoid fractures occurred over a wide age range. The youngest patient was fifteen, and the oldest, seventy-nine. The average age was forty-four and seven-tenths years. More than half the cases were in males. Ten of the 15 patients had radial fractures of the Colles type. 1 was impacted without displacement, 5 had backward tilting of the distal fragment, and 4 had comminuted "T" fractures involving the joint. Of the remaining 5, 3 had a chauffeur fracture of the radial styloid, 1 had a Barton fracture of the dorsal articulating surface, and there was 1 epiphyseal fracture with wide displacement of the distal epiphysis and a dorsal metaphyseal fragment. All these cases resulted from a fall on the outstretched hand except for the fractures of the radial styloid, which occurred from blows forcing the hand into dorsal and radial flexion. One case, similar to that of Cleveland,⁶ had associated fractures of the greater multangular, the scaphoid and the radius (Colles type). Another case (Fig 1) illustrates a different line of force, with fractures of the base of the third metacarpal, the waist of the scaphoid and a comminuted Colles fracture involving the joint. This case required four and a half months of immobilization for bony union to occur in the scaphoid.

DIAGNOSTIC PROBLEM

It is hard enough to diagnose a fracture of the scaphoid when the radius is not broken. A case with separation of the scaphoid fragments presents no diagnostic difficulty, but the barely visible hairline, which may not develop until many days after injury, is a more serious problem. The pain and swelling of the radial fracture mask the signs and symptoms referable to the scaphoid, and the surgeon is apt to see at a glance the gross deformity of the radius without bothering to look farther for a suspicious hairline in the scaphoid. It is very easy to concentrate attention on the radius to the exclusion of the carpus in check x-ray films, in which oblique views are seldom required. A policy of taking frequent careful scaphoid series is the only program that can prevent most errors.^{2, 6, 8}

THERAPEUTIC PROBLEM

None of the authors who discuss the occurrence of fractures of the scaphoid complicated by a comminuted Colles fracture mention the paradox of

*Resident surgeon, Johns Hopkins Hospital; formerly fellow Orthopedic Service, Boston City Hospital.

†Surgeon in-chief, Orthopedic Service, Boston City Hospital.

cipitated pertussis organisms used was only 20-000 000 000, these results are impressive even by the most conservative standard

Immunization of Young Infants

It has long been recognized that young infants have little or no inherited immunity to pertussis and that most deaths and complications occur in this age group. Over 50 per cent of all (pertussis) deaths occurred under six months of age and over 75 per cent died before reaching the age of one year.¹³ It was formerly believed that infants under six months did not respond effectively to pertussis immunization, this may well have been true of earlier and less effective vaccines. At all events numerous recent reports have testified to the contrary. Sako¹⁴ following up his earlier studies in this field reports agglutinin responses in 8690 Negro children immunized at ages ranging from two weeks to five years. No significant differences in antibody response of children immunized at different ages were found. Four hundred and ninety-three children immunized before three months of age were known to have been exposed to pertussis within the household, and were compared to 438 exposed controls of comparable age. Pertussis occurred in 13.2 per cent of the vaccinated children and 89.7 per cent of the controls. Incidentally the pertussis attack rate in the former was in general inversely correlated with their agglutinin titers — apparently the first strong evidence that agglutinin titers and protection against clinical pertussis are correlated. Sauer¹⁵ Adams¹⁶ di Sant' Agnese^{91 157 158} and Halpern¹⁵⁹ among others, have also reported successful immunization of young infants, as judged by antibody titers or skin tests. Both Sauer and Sako emphasize the superior agglutinin titers produced by alum-precipitated vaccine as compared to fluid vaccine.

Most investigators have agreed with Sauer¹⁶⁰ in finding a poorer antibody response in early infancy than in late infancy and childhood only. Sako¹⁵⁴ reporting no evidence of such differences. To guard against early relapse of immunity in young infants given pertussis vaccine many workers have stressed the importance of giving a booster dose of pertussis vaccine a year or so later. Confirmation of the efficacy of such a booster dose is presented by Sako,¹⁵⁴ by di Sant' Agnese^{91 158} and by Kendrick and her associates,¹⁹¹ who found ample antibody responses to such injections, the response in di Sant' Agnese's series, however being definitely better in infants first immunized at six to twelve months.

Preparation and Testing of Vaccine

Obviously, even the best results reported with pertussis vaccine are not wholly satisfactory. The principal difficulty at present lies in insufficient

knowledge regarding the antigenic factors responsible for producing immunity to the disease. Recent advances in the purification of the endotoxin¹⁹² and the soluble antigens¹⁹³ of the pertussis bacillus may furnish a basis for more exact knowledge in this respect. Meanwhile, experiments with cruder preparations or whole organisms have contributed much fundamental knowledge. Proom¹⁹⁴ has shown that studies of experimental infection may give different answers depending on the technic employed — for example, intraperitoneal injection of live pertussis organisms in a mouse produces chiefly a toxemia combated successfully by antitoxin whereas intranasal infection is best counteracted by antibacterial antibody. Evans¹⁹⁵ long experienced in the study of pertussis toxin has recently added to the accumulation of evidence that antitoxic antibodies are apparently not of material significance in human infection or immunity and Verwey and Thiele¹⁹⁶ have added to the parallel evidence in animals. Gray¹⁹⁷ in animal experiments has reaffirmed the importance of young virulent cultures in the preparation of potent immunizing agents and his more recent observations suggest that much is yet to be learned regarding the ideal conditions for production of vaccine.¹⁹⁸ A new and somewhat obscure factor has been added with the finding that both virulence and antigenicity of pertussis bacilli are closely related to a hitherto unrecognized property — the ability of pertussis cultures to agglutinate avian or mammalian red cells.¹⁹⁹ If this can be adequately confirmed it may provide an extremely useful tool for further evaluation of stock cultures for vaccine production for screening of vaccine batches for potency and perhaps for confirmation of the clinical diagnosis of pertussis. The procedure is as simple as the Hirst test to which it is analogous from a technical viewpoint.

Potency evaluation of pertussis vaccines by a laboratory technic has long been beset by difficulties in reproducing a clear-cut disease in animals as a challenge of experimental immunization. Kendrick and her associates²⁰⁰ have carried out an extensive study, in collaboration with numerous other laboratories using the intracerebral route for injection of the challenge organisms in mice, their results indicate marked differences between different batches of vaccine. However the highly artificial character of the intracerebral route in contrast to the nasal route for example leaves room for dispute concerning which is the most useful in performing a potency test. The nasal route has long been known and is widely employed^{191 197}, to date it has shown the disadvantage of giving highly variable results. When the inherent difficulties in evaluating the potency of pertussis vaccine can be resolved and laboratory and field trials have been extensively correlated, it will be possible to make more rapid advances in preparation of the vaccine or of its active fractions.

MEDICAL PROGRESS

ACTIVE IMMUNIZATION (Continued)

GEOFFREY EDSALL, M D *

BOSTON

PERTUSSIS

Results Obtained with Vaccine

Opinion regarding the efficacy of pertussis vaccine is still far from unanimous. Bell,⁶ in a recent review of the subject, stated that "health officers have sufficient evidence to permit the use of [pertussis vaccine]" Lewis¹⁷⁴ sums up the conservative view, more widely held in England, that there is still a need for large-scale field trials, and that until these have been carried out no widespread campaign for whooping-cough inoculation in that country is justified. Parish¹⁷⁵ similarly expresses the belief that the laboratory and clinical evidence to date do not prove the effectiveness of specific immunization against whooping cough. Both workers have doubtless been considerably impressed by the flatly negative results obtained in the first extensive controlled study of the vaccine in England, reported three years ago.¹⁷⁶ This point of view was strongly expressed in a critical editorial, concurrent with the English report, which pointed out defects in many of the best known American studies of the vaccine—differences in family size or in time of observation of vaccinated and control groups, lack of any genuine controls and so forth.¹⁷⁷ It is true that some reports of apparently favorable results from pertussis vaccination do not stand up well to critical examination. As an example, one may cite the 436 immunized Winnipeg children observed by Brereton¹⁷⁸ in whom no whooping cough occurred in two and a half years, despite the occurrence of 1171 cases in the city during this period. Such findings suggest—but in no sense prove—that the vaccine used was effective. One may calculate that there should have been about 17 cases among his patients in this period if the vaccine had been ineffective—and if his patients were a representative sample of the child population. No evidence is presented, however, that his patients were not unduly shielded from infection (for example, that they had few or no siblings and limited contacts with other children) or were otherwise not representative of the community as a whole. More convincing, although likewise lacking in controls, is the experience of Tucker,¹⁷⁹ who has seen only 70 cases of pertussis among 5590 children immunized during the last thirteen years. A situation more subject to statistical evaluation is reported by Rodman, Bradford

and Berry,¹⁸⁰ who observed a public-school outbreak, in which the incidence of pertussis was twice as high in the unvaccinated as in those who had received any pertussis vaccine, and almost six times as high as it was in those whose immunization had included at least 50,000,000,000 organisms. However, since the entire outbreak included only 57 cases, the results must be accepted with some reservations. During another outbreak, reported by Lapointe,¹⁸¹ in a foundling home in Quebec, 82 per cent of 550 unimmunized children and infants contracted pertussis, with 5 deaths, whereas no more than 10 per cent of the 100 vaccinated children developed the disease. Despite the lack of a clear-cut basis for comparison between the controls and the children vaccinated, this report is hard to explain except on the assumption that vaccination was highly effective.

Bell⁸² has recently reported a study that approaches the epidemiologist's ideal for evaluation of an immunization procedure. A diphtheria-immunization campaign for infants aged two to twenty-three months was conducted through a group of clinics in Norfolk, Virginia, with the co-operation of the local health authorities. Doctors and nurses were furnished alum-precipitated toxoids for the program, with instructions to administer certain lots if the baby was born in an "odd" month (such as January, March or May) and other specified lots if the birth had been in an "even" month. Neither the parents nor the local health authorities were informed that one set of lots also contained pertussis vaccine. The physician in charge of the study, who saw most of the cases of whooping cough reported by visiting nurses in the immunized children, did not himself know which lots had contained pertussis vaccine. In this fashion it was possible to ensure absolute impartiality on the part of the examining physicians and others engaged in collecting field observations. Statistical analysis showed that both groups were essentially identical in sex, age distribution, color, order in family, age at first inoculation, incidence of other common contagious diseases, and numerous other factors that might have biased the results of the study. These results showed an over-all incidence of pertussis in the controls, which was 3.45 times that in the patients receiving pertussis vaccine. If only frank severe pertussis was counted, the incidence was 8 times as great in the controls as in the vaccinated. In view of the fact that the total dose of alum-pre-

*Director, Division of Biologic Laboratories, Massachusetts Department of Public Health; assistant professor of public health bacteriology, Harvard School of Public Health.

Immunization with Specific Polysaccharides

As the number of recognized types of pneumococcus increased, and it became established that each was immunologically distinct, the possibility of effective human immunization against pneumococcal pneumonia was generally laid aside, and efforts were directed toward its treatment by physiologic and serologic means. However, the chemical studies of Dochez, Avery and Heidelberger^{216 217} made available in purified form the specific soluble capsular polysaccharides that characterized several of the common types of pneumococcus. Francis and Tillett²¹⁸ showed that intracutaneous injection of these preparations into patients with pneumonia gave rise to antibody formation, this was confirmed, in normal as well as sick persons, by Finland and Sutliff²¹⁹. Earlier disagreement regarding the antigenicity of such preparations in mice—the customary test animal²²⁰—was shown to be due to the existence of two forms of the antigen: the natural acetylated form, and a deacetylated form resulting from treatment with alkali.²²¹ Both were found to be antigenic in man, but only the former induced antibodies in mice.²²²

Felton^{223 224} carried out extensive laboratory-controlled studies on the use of specific polysaccharides of pneumococcus in man. He demonstrated that significant antibody responses could be induced by doses of polysaccharide that were reasonably well tolerated by the recipients. His work formed the basis for collaboration with Army Medical Corps personnel, in a study of immunization against Types 1 and 2 pneumonia in about 70,000 males, mostly under twenty years of age, in New England and the far West.²²⁵ The incidence ratio of Types 1 and 2 pneumonia in 14,000 controls as against 10,700 persons vaccinated in New England was about 1.7:1, but in the much larger western groups (26,000 control and 18,000 vaccinated subjects) the relative incidence was 9:1. However, because of the short season of observation, the lack of strict alternation in selecting the controls, and other factors, these impressive results must be taken with some reservations.

Similar studies on a smaller scale, carried out in several localities over the past decade, have given varying results, which either were not numerically significant or might readily have resulted from natural fluctuations in the incidence of pneumonia. However, there have recently been reported two series of studies in which the results obtained appear to be significant. MacLeod and his associates²²⁶ immunized 8586 soldiers at a technical school, with 0.03 to 0.06 mg. each of Types 1, 2, 5 and 7 polysaccharides, 8449 controls being injected with phenolized saline solution. Age distribution, duration of service and so forth were closely comparable in both groups. The high incidence of pneumonia at this school in two preceding years favored such

an immunization study. Laboratory studies, both on the Army group and on civilian volunteers, had shown, moreover, that such inoculation was followed in almost all cases by striking increases in the specific precipitating antibody titer in the subjects' serum.^{227 228} The incidence of the four types in question, during an average stay of twenty-four weeks per man, was $\frac{1}{4}$ cases in the vaccinated, and 56 in the controls. Furthermore, the carrier rate dropped significantly in the vaccinated group, this drop no doubt contributing to the apparent decrease in the number of cases of Types 1, 2, 5 and 7 in the controls, which was only 17 per cent of the expected rate based on the incidence of higher types not affected by the study. Taking the bacteriologic and epidemiologic data as a whole, the effect of polysaccharide immunization in this group appears to have been striking.

Kaufman²²⁹ has recently reported a six-year study of immunization in elderly persons with Types 1, 2 and 3 polysaccharides. A group of 5750 immunized subjects contracted 3 cases of Type 1, 2 or 3 pneumonia (and 31 cases of other types of pneumococcal pneumonia) during this period, whereas 5153 controls experienced 96 cases of pneumococcal pneumonia, of which 33 were Types 1, 2 and 3.

Serum titrations before and twenty-one days after immunization showed increases of several hundred times in antibody content after injection of the antigens. Local reactions occurred in 5 per cent, and general reactions in 2 per cent of the subjects. In patients who developed pneumonia, the duration of illness and the severity of toxemia were less in the immunized than in the controls. Total person-years of observation are not given, nor is the method of selection of controls stated, the peculiarly higher incidence of "higher types" of pneumonia among the controls is not explained.

Nevertheless, the sum total of all available observations cited above strongly indicates that immunization with pneumococcal type-specific polysaccharides exerts a strong protective effect in man against the homologous types of pneumonia. Such polysaccharide preparations have recently been put on the market, in two forms: a mixture of Types 1, 2, 3, 5, 7 and 8, primarily for use in adults and adolescent children, and a mixture of Types 1, 4, 6, 14, 18 and 19, for protection of infants and young children against the types to which this age group is most subject. Both these multiple-antigen preparations have been shown to be effective in stimulating antibody production.²³⁰ The Massachusetts Department of Public Health has recently called attention to the value of such immunization, recommending that it be considered in the elderly, the very young, special occupational groups with high natural incidence of pneumococcal pneumonia and patients about to undergo major surgical operations.²³¹ If immunization is employed for this latter category, however, it should be borne in mind

Meanwhile, the possibility has arisen that pertussis vaccines — like typhoid vaccines — will have to be prepared in polyvalent form. Wilson and Miles²⁰¹ have noted that it may ultimately prove necessary to include the parapertussis organism in pertussis vaccines. With such a thought in mind, Rambar, Howell and Denenholz²⁰² have prepared a combined pertussis-parapertussis vaccine that produced clear-cut opsonic antibody rises against both components and actually appeared to induce a better response against the pertussis bacillus than that obtained with the monovalent pertussis vaccine.

Reactions

Since the start of extensive whooping-cough immunization, reactions to the injection of the vaccines used have been sufficiently frequent to cause occasional concern. Local tenderness and swelling have been ascribed to the use of too concentrated a suspension, or to the irritating effects of alum precipitates. Lapin²⁰³ found that variations in concentration of organisms from 15,000,000,000 to 40,000,000,000 per cubic centimeter caused no significant difference in incidence of local or general reactions. He believes that the irritating effects of alum are due chiefly to its low pH. Sterile abscesses (or "antigenic cysts"), which may occur in as many as 2 or 3 per cent of cases, are usually associated with alum-precipitated preparations. Tucker¹⁷⁹ and Sauer¹⁸⁵ stress the importance of injecting distally, and carefully wiping free alum off the needle tip before injection, to avoid alum abscesses. Sako¹⁸⁴ employed these precautions as well as the recommendation of Bell¹⁶² that deep subcutaneous injection be employed, and he added the precaution of taking especial care to avoid intracutaneous injection. Following these precautions, he observed 1.5 per cent "alum abscesses" in 2021 inoculations. On the other hand, other reactions were more than twice as frequent with fluid vaccine as with alum-precipitated material.

A matter of more serious concern is the occasional occurrence of convulsions or, more rarely, of a frank encephalopathic syndrome following pertussis vaccination. Sako²⁰⁴ noted 2 cases of vomiting, diarrhea and convulsions in his earlier series, and several similar reports have been cited by Byers and Moll,²⁰⁵ including 4 fatal cases. Brody and Sorley²⁰⁶ reported the case of a ten-month-old infant who exhibited generalized hypotonia, somnolence and difficulty in micturition following each of three doses of pertussis vaccine. At the age of forty-three months he received a skin test with pertussis vaccine, after which a generalized flaccid paralysis developed, the patient dying of bronchopneumonia seven weeks later. Byers and Moll²⁰⁵ have collected 15 cases of convulsions following pertussis-vaccine inoculation, which were seen at the Boston Children's Hospital over a ten-year period. Thirteen exhibited residual damage when last seen. It is difficult to

evaluate such findings, since many other causes of encephalopathy exist, and the association with pertussis vaccination might conceivably be one of coincidence. The absence of comparable reports from other communities may be reassuring, but this cannot be evaluated until others have searched for this syndrome as extensively as Byers has done. Approximately 40 cases of possibly similar nature have been disclosed through individual case reports²⁰⁷ and an extensive questionnaire sent to some 55 physicians whose collective experience covers at least several hundred thousand injections.²⁰⁸ The net impression gained from this survey is that such reactions may occur, but that they are exceedingly rare. Meanwhile, the National Institute of Health has during the two years developed a toxicity test for pertussis vaccines. The application of this test may serve to eliminate excessively toxic batches of vaccine, which may have been responsible for reactions of the type described.

PNEUMOCOCCAL PNEUMONIA

Immunization with Bacterial Suspensions

The capacity of extracts from cultures of pneumococcus to furnish protection against pneumococcal infection in animals was demonstrated over fifty years ago.²⁰⁹ An understanding of the immunologic and chemical properties of the specific soluble substance of the pneumococcus did not come about until much later, however, hence early attempts to immunize human beings against lobar pneumonia were carried out with the use of whole bacterial vaccines. The most widely cited of these studies^{210, 211} yielded promising results. Cecil and Austin,²¹⁰ for example, in a study at Camp Upton, inoculated 12,519 "stable" troops with a vaccine composed of Types 1, 2 and 3 organisms, using about 20,000 other troops (of which perhaps 75 per cent were "stable") as controls. The incidence of Types 1, 2 and 3 pneumonia, over a period of ten weeks, was nil in the vaccinated and 18 in the comparable stable control group. However, since the incidence of other types of pneumonia — particularly those due to the streptococcus — was likewise greater in the controls than in the vaccinated, the validity of this experiment is open to question. The South African studies of Lister and his colleagues^{211, 214} cover longer periods and larger groups, among native laborers in the goldfields. However, no actual controls to these groups were set up, so that the results from vaccination had to be evaluated by comparison with the incidence of pneumonia in unvaccinated mine groups, or in years prior to vaccination. Although the results strongly suggested that vaccination was materially effective in some cases at least, there are alternative explanations for the figures observed, and there are some figures showing less promising results.²¹⁵ Hence this series of studies must also tentatively be regarded as inconclusive.

Immunization with Specific Polysaccharides

As the number of recognized types of pneumococcus increased, and it became established that each was immunologically distinct, the possibility of effective human immunization against pneumococcal pneumonia was generally laid aside, and efforts were directed toward its treatment by physiologic and serologic means. However, the chemical studies of Dochez, Avery and Heidelberger^{16, 17} made available in purified form the specific soluble capsular polysaccharides that characterized several of the common types of pneumococcus. Francis and Tillett¹⁸ showed that intracutaneous injection of these preparations into patients with pneumonia gave rise to antibody formation, this was confirmed in normal as well as sick persons, by Finland and Outliff¹⁹. Earlier disagreement regarding the antigenicity of such preparations in mice — the customary test animal²⁰ — was shown to be due to the existence of two forms of the antigen: the natural acetylated form and a deacetylated form resulting from treatment with alkali.²¹ Both were found to be antigenic in man, but only the former induced antibodies in mice.²²

Felton^{23, 24} carried out extensive laboratory-controlled studies on the use of specific polysaccharides of pneumococcus in man. He demonstrated that significant antibody responses could be induced by doses of polysaccharide that were reasonably well tolerated by the recipients. His work formed the basis for collaboration with Army Medical Corps personnel, in a study of immunization against Types 1 and 2 pneumonia in about 70,000 males, mostly under twenty years of age, in New England and the far West.²⁵ The incidence ratio of Types 1 and 2 pneumonia in 14,000 controls as against 10,700 persons vaccinated in New England was about 1.7:1, but in the much larger western groups (26,000 control and 18,000 vaccinated subjects) the relative incidence was 9:1. However, because of the short season of observation, the lack of strict alternation in selecting the controls, and other factors, these impressive results must be taken with some reservations.

Similar studies on a smaller scale, carried out in several localities over the past decade, have given varying results, which either were not numerically significant or might readily have resulted from natural fluctuations in the incidence of pneumonia. However, there have recently been reported two series of studies in which the results obtained appear to be significant. MacLeod and his associates²⁶ immunized 8586 soldiers at a technical school, with 0.03 to 0.06 mg. each of Types 1, 2, 5 and 7 polysaccharides, 8449 controls being injected with phenolized saline solution. Age distribution, duration of service and so forth were closely comparable in both groups. The high incidence of pneumonia at this school in two preceding years favored such

an immunization study. Laboratory studies, both on the Army group and on civilian volunteers, had shown, moreover, that such inoculation was followed in almost all cases by striking increases in the specific precipitating antibody titer in the subjects' serum.^{27, 28} The incidence of the four types in question, during an average stay of twenty-four weeks per man, was $\frac{1}{4}$ cases in the vaccinated, and 56 in the controls. Furthermore, the carrier rate dropped significantly in the vaccinated group, this drop no doubt contributing to the apparent decrease in the number of cases of Types 1, 2, 5 and 7 in the controls, which was only 17 per cent of the expected rate based on the incidence of higher types not affected by the study. Taking the bacteriologic and epidemiologic data as a whole, the effect of polysaccharide immunization in this group appears to have been striking.

Kaufman²⁹ has recently reported a six-year study of immunization in elderly persons with Types 1, 2 and 3 polysaccharides. A group of 5750 immunized subjects contracted 3 cases of Type 1, 2 or 3 pneumonia (and 31 cases of other types of pneumococcal pneumonia) during this period, whereas 5153 controls experienced 96 cases of pneumococcal pneumonia, of which 33 were Types 1, 2 and 3.

Serum titrations before and twenty-one days after immunization showed increases of several hundred times in antibody content after injection of the antigens. Local reactions occurred in 5 per cent, and general reactions in 2 per cent of the subjects. In patients who developed pneumonia the duration of illness and the severity of toxemia were less in the immunized than in the controls. Total person-years of observation are not given, nor is the method of selection of controls stated, the peculiarly higher incidence of "higher types" of pneumonia among the controls is not explained.

Nevertheless the sum total of all available observations cited above strongly indicates that immunization with pneumococcal type-specific polysaccharides exerts a strong protective effect in man against the homologous types of pneumonia. Such polysaccharide preparations have recently been put on the market, in two forms: a mixture of Types 1, 2, 3, 5, 7 and 8 primarily for use in adults and adolescent children, and a mixture of Types 1, 4, 6, 14, 18 and 19 for protection of infants and young children against the types to which this age group is most subject. Both these multiple-antigen preparations have been shown to be effective in stimulating antibody production.³⁰ The Massachusetts Department of Public Health has recently called attention to the value of such immunization recommending that it be considered in the elderly, the very young, special occupational groups with high natural incidence of pneumococcal pneumonia and patients about to undergo major surgical operations.³¹ If immunization is employed for this latter category, however, it should be borne in mind

that such immunity as may develop cannot be expected to appear for at least nine days, and will probably not be adequate in less than two weeks after inoculation. Also, it is imperative to re-emphasize the fact that immunity induced by pneumococcal polysaccharides is effective only against the homologous types of pneumococcus, except where a low degree of cross immunity against related types may be induced.

RABIES

Present Situation, Dog Vaccination

Although rabies has been on the wane in certain areas, notably New England, it has been definitely on the increase elsewhere in the United States during the last few years. This trend is clearly set forth in a recent review by Johnson,²³² who summarizes the epidemiology, etiology, laboratory characteristics, symptoms in animals, diagnostic features and preventive measures applicable to the disease, in a presentation distinguished for its clarity and readability. The review calls attention to the marked increase in animal rabies in recent years over the United States as a whole, the number of reported rabid animals throughout the country was higher in 1944 than in any previous year on record. In fact, the spread of this disease among animals in New York, Pennsylvania, Maryland, Virginia and other states in the last few years has led to several studies and conferences from which have come broadly conceived, long-range programs for control of the disease on a nationwide basis.²³³⁻²³¹ Such control is needed not only because of the risk to human life engendered by the disease, and the discomfort, inconvenience, expense and actual danger incurred by persons receiving the vaccine, but also because of the considerable loss in farm stock caused by rabies: there were 2800 reported deaths from this disease among cattle alone during the period 1938-1945 inclusive, the actual number being unquestionably much higher.

Johnson's review, the New York Academy of Medicine Report, and the April 1947 conference headed by Dr. R. A. Kelser, all agree on the following recommendations:

Rabies control can only be accomplished effectively through federal participation and co-ordination — the agencies most obviously concerned being the United States Public Health Service, the Bureau of Animal Industry and the United States Fish and Wildlife Service.

Reporting of animal rabies should be universally required.

Dog licensing should be enforced, stray dogs should be impounded, and dog quarantine should be applied, especially in areas where animal rabies is present.

Dog vaccination should be encouraged on the widest possible scale, and at little or no cost

to the dog owner (since few owners will avail themselves of the service otherwise). In urban areas, dog licenses should be made contingent upon vaccination.

A widespread and generalized public-education program should be undertaken, particularly to acquaint the public with the need for control of rabies, the advantages of rabies control to dogs as well as man, and the now proved value of dog vaccination. Johnson²³² remarks upon the still persistent belief that dog vaccination is ineffective — a belief based upon the poorly conceived experiments and low-potency vaccine of some years ago. The effectiveness of a potent vaccine, properly used, is shown in an experiment of his, referred to elsewhere²³³, 52 vaccinated dogs, along with 52 unvaccinated dogs, were injected with street virus one year after vaccination. Death occurred in 11.5 per cent of the vaccinated as against 79 per cent of the control animals. Such experiments as these and other experimental and field studies previously cited¹¹ have established the efficacy of dog vaccination. Its practical value has also been recently affirmed in New York State, in ten counties having 78 per cent of the enumerated dogs vaccinated, the incidence of rabies in unvaccinated dogs was fifteen and eight-tenths times that in the vaccinated animals.²³⁵ The value of protection of one's pets is also illustrated in the saga of a rabid dog that recently roamed through three townships before it was killed, and bit 13 unvaccinated dogs in succession — several of which had to be destroyed as a result.²³¹ Effective control of rabies, however, cannot be achieved merely through local or even statewide programs, since rabid animals do not recognize state boundaries. Hence the recommendation^{232, 231} for federal rabies-control legislation is especially pertinent at this time of increasing prevalence of the disease in animals.

Methods of Preparing Rabies Vaccine

The factors that may influence the potency of rabies vaccine continue to be under scrutiny. Habel²³⁷ compared the potency of vaccines inactivated by ultraviolet irradiation, by phenol and by chloroform, and found the ultraviolet-treated material to be greatly superior. A new method of inactivation, employing nitrogen mustards, has been applied experimentally,²³⁸ but has not yet had extensive trial in either animals or man.

The choice of virus strain for preparation of vaccine may still be open to question, since Habel and Wright²³⁹ found marked differences in immunizing potency of six different strains in routine use. Their paper gives a detailed description of what is now the standard method for testing the potency of rabies vaccine. The standard of potency set under this method is considerably higher than the average level that prevailed before the method was pro-

nulgated so that the vaccines now obtainable may be used with far greater assurance of efficacy than before

Although greatly improved in potency the currently available vaccines contain large amounts of impurities in the form of brain-tissue constituents. Because of the numerous recent studies noted below, which indicate that brain-tissue injections may induce severe damage to the nervous system present interest is focused on the problem of purifying the vaccine. Two recent reports^{240 241} have described methods for removing most or all of the lipid constituents of the vaccine, by extraction with organic solvents at low temperatures. The resulting preparation appears to be actually more potent than the crude material²⁴⁰

Reactions Following Antirabic Vaccination

Paralytic accidents following administration of rabies vaccine have been found to occur about once in 5800 cases, with death resulting in about 1 out of each 23,000 cases treated²⁴². The incidence fluctuates greatly, however, after more than a decade during which no fatal cases were noted in Massachusetts, 2 deaths occurred in 1947²⁴³. A high incidence of such accidents has also been recently noted elsewhere^{244 245}. Irrespective of whether such accidents are sporadic or represent a definite upward trend, the 2 recent deaths in this state have served as a reminder that the use of rabies vaccine must be considered in the light of the total situation. In Massachusetts, for example, endemic animal rabies has not been present for four or five years. Here rabies vaccine can wisely be withheld except in cases of proved exposure to the disease, or in persons bitten in the Berkshire area, which is subject to reinfection at any time by rabid animals from the neighboring endemic foci in New York State. The advisability of such a conservative review of the problem has been stressed by the Massachusetts Department of Public Health²⁴³ and in an accompanying editorial in the *Journal*²⁴⁶. Sellers,²⁴⁷ whose experience has been gained in one of the most heavily rabies-infected areas in this country, shares the view that antirabic vaccination is not to be lightly undertaken, stating his belief that "it has caused more deaths than has rabies when given to persons only indirectly or remotely exposed". He notes that in the 7 cases of treatment paralysis that he has followed, 4 patients died, only 2 of these 7 were in persons bitten by rabid dogs the other 5 (including 3 of the deaths) occurring in persons only remotely exposed to rabies.

For a number of years it has been suspected that encephalitis following rabies vaccination might be the consequence of an iso-allergic reaction resulting from injection of brain substance, which is organ-specific rather than species-specific. Some years ago Rivers and his associates^{248 249} succeeded in producing lesions in the nervous system of

monkeys by repeated injections of suspensions and alcoholic extracts of rabbit brain. Recently, Morgan²⁵⁰ and Kabat, Wolf and Bezer²⁵¹ have produced encephalomyelitis in monkeys by a few injections of brain substance combined with tubercle bacilli paraffin oil and an emulsifying agent, according to the technic developed by Freund¹⁴⁸. Using guinea pigs Freund et al²⁵² produced meningo-encephalitis and paralysis of the hind legs with only one injection of such an emulsion of brain tissue. Furthermore some of the animals surviving the first injection developed acutely fatal reactions after reinjection of the same material three or four weeks later. Kopeloff and Kopeloff²⁵³ confirmed these findings in guinea pigs, and produced paralysis by similar means in rabbits. Recently, Jungblut²⁴ has added further confirmatory evidence of the sensitizing capacity of brain substance. Thus, there are ample experimental data to indicate that repeated injections of brain substance can, under certain as yet obscure conditions, induce an iso-allergic reaction that may result in varying degrees of destruction of the gray and white matter of the brain or spinal cord. It is, of course, yet to be proved that human paralytic accidents are caused by such a reaction, but the available evidence points in this direction. Still to be explained however, is the relative rarity of such reactions.

The experiments cited provide a basis for attempting to define the specific substance or substances in brain tissue that are responsible for these reactions, and to develop physical or chemical methods for their removal. Recent purification studies^{240 241} may lead to such findings, but this has as yet to be determined. A different approach to the solution of this problem is suggested by Chen-Jen and Zia,²⁵⁵ who have prepared a potent vaccine from rabies-infected brains of guinea-pig fetuses, fetal brain tissue having been found by Zia²⁵⁶ and others²⁵⁷ to be apparently nonantigenic. Meanwhile, this and other aspects of the problem are now under active investigation in several laboratories, and it is to be hoped that these studies will be fruitful.

SMALLPOX

Recent Occurrence of Virulent Smallpox in the United States

On the whole, the incidence of smallpox has continued to decline in the continental United States during the last few years. This decline has recently been the subject of an editorial comment²⁵⁷ which cited Dr. Benjamin White's²⁵⁸ reminder of over twenty years ago, that smallpox is never conquered but "is at best only held at bay by the continued practice of vaccination". Recent experience in the Orient, on the West Coast of this country and later in New York City has amply confirmed this already well established fact. The severity of smallpox as seen in the Orient, as well as the frequency

of its occurrence in presumably vaccinated persons, was vividly described a year ago by Agerty,²⁶⁹ who observed 17 cases with 10 deaths among American personnel in Japan. Only 4 of these patients had histories or scars indicating that they had been vaccinated in childhood. All but 3 had been recorded as having been vaccinated within the preceding two years, in 2 vaccinoid reactions had developed, the other 12 being noted as "immune," "doubtful" or "unsuccessful" (The probable significance of "immune" reactions is discussed below.) Reports from other sources have indicated scattered failures to protect American personnel in the Orient by the use of the standard vaccination procedure and the vaccine available at the time. Hence it was not surprising that cases appeared among servicemen returning to the West Coast. Such cases caused a small outbreak in San Francisco early in 1946,²⁶⁰ and a much larger one in and around Seattle.^{261, 262} The latter outbreak produced at least 65 cases with 20 deaths (a 30.8 per cent case mortality) and took four months to stamp out. An incidental result of this outbreak was an unprecedentedly successful vaccination campaign in neighboring British Columbia, which probably reached 250,000 people. This may be contrasted with the 80,000 in the province who submitted to vaccination fourteen years earlier in the presence of an actual smallpox outbreak. Apparently, the public at large has become widely educated, in the interval, regarding the wisdom of being vaccinated.²⁶³

If proof of this acceptance of vaccination were needed, the New York City outbreak of March-April 1947 has furnished it. A total of 8 confirmed cases in New York City, and 4 outside the city, occurred over a period of about six weeks. The findings in most of these cases have been thoroughly expounded and discussed in a clinicopathological conference.²⁶⁴ The first case was atypical and not recognized until secondary cases were diagnosed, by which time it was evident that numerous scattered tertiary cases might be expected to appear. The decision was therefore made to vaccinate the entire city. Over 6,000,000 people were actually vaccinated during the following two weeks.²⁶⁵ This was accomplished by extraordinary efforts on the part of local medical and health personnel and also of the producing firms, which were faced with a demand for vaccine unparalleled both in size and in urgency. This outbreak caused widespread alarm elsewhere, increases in vaccination demands being observed at least as far away as Michigan. Although states such as Massachusetts and Michigan, having their own production facilities, were able — with difficulty — to keep pace with the demand, many other communities saw their supplies of vaccine temporarily exhausted. The experiences of the last two years suggest that it is entirely possible for several virulent foci of smallpox to be established in this country at about the same time. In

such an event, vaccine supplies would certainly be temporarily inadequate. This possibility focuses attention on the importance of maintaining an immune population, by vaccination in infancy and periodic revaccination.²⁶⁶ This is clearly demonstrated by the New York experience, which showed that perhaps 50 per cent of the people in that urban area were susceptible to infection, as indicated by either a primary or a vaccinoid reaction.⁶

England has had similar but considerably more numerous experiences, as indicated in several excellent reports of outbreaks of virulent smallpox in that country.²⁶⁷⁻²⁷² Mortality rates have been high — for example, 3 deaths in 11 cases,²⁶⁸ 9 in 31 cases,²⁶⁹ and 6 in 30 cases.²⁷¹ Control has been difficult owing to unfamiliarity of local physicians with the diagnosis, to the high level of susceptibility in England, where compulsory vaccination has always been resisted and in fact has recently been abandoned²⁷³, and to the marked and prolonged contagiousness of infected materials, smallpox crusts sometimes remaining infectious for as long as a year.²⁷⁴

Interpretation of Vaccination Reactions

The extensive need for mass vaccination during and after World War II and the many opportunities for contracting smallpox confronting persons hitherto safe from the disease have led to an extensive and critical re-evaluation of the phenomenon of vaccination. The official requirement of a vaccination certificate, imposed on an unprecedented number of travelers, gave rise to various problems outstanding among which was the question of how to interpret an "unsuccessful vaccination," especially in persons who failed to develop a "take" after repeated attempts. For example, Broom²⁷⁵ reports the experience resulting from vaccinating 1221 UNRRA personnel, 238 of whom did not "take." On revaccination of 201 of this group, 80 per cent were again negative. Broom suggests that such persons are "insusceptible" to vaccination, and that allowance should be made for such a classification on vaccination certificates. He is supported in this by Mitman,²⁷⁶ MacKenzie,²⁷⁷ Stuart²⁷⁸ and indirectly, also by Cavaillon,²⁷⁹ who suggests that it may be desirable to indicate, "in unsuccessful cases, that vaccination had been carried out twice or several times, at certain intervals." In fact, some observers have regarded "no reaction" as synonymous with immunity,²⁸⁰ but such views run into direct conflict with the prevailing belief, at least in this country,²⁸¹ which holds that unsuccessful vaccination is never to be accepted as final and merely calls for another attempt. However, it must be recognized that such a doctrine can be incompatible with the realities of human activity, as the medical officer of the Port of London has cogently pointed out²⁸², for example, a traveler cannot ordinarily

postpone a sailing date until a long series of attempts at revaccination is at last successful

A significant portion of the difficulty in obtaining satisfactory "takes" appears to derive from ineffective technic of vaccination. Several recent English communications have called attention to the deficiencies of the scratch technic which has been generally used in that country. Mole,²⁵³ performing alternate scratch and multiple-pressure vaccinations, obtained 83 per cent "takes" by the scratch method as against 94 per cent by the multiple-pressure technic. Vaughan²⁵⁴ and Lovett²⁵⁵ similarly report repeated successes in multiple-pressure vaccination, in persons previously scratched unsuccessfully by the older technic. Within the past year the use of the multiple-pressure method (which Parish²⁵⁶ and others in England have advocated for several years) has been officially recommended by the British Ministry of Health²⁵⁷ and by an expert committee of WHO on International Epidemic Control.²⁵⁸ It will be of interest to observe whether the problem of "insusceptibility" is diminished in the future as a result of this trend. In justice to the scratch technic, however, it should be noted that on occasion almost complete success has been achieved by its use. When smallpox appeared on a troopship bound for New Zealand, 94 per cent of the 1648 men on board were successfully vaccinated by the scratch method on the first attempt.²⁵⁹

A subtler problem arises from the interpretation of the so-called "immune reaction"—the raised papule that reaches its height on the second or third day and then subsides without vesicle formation. This reaction is very widely accepted as adequate evidence of immunity. Doraisingham,²⁶⁰ for example, notes that smallpox in Singapore has been extremely rare for thirty years, in a population of which 73 per cent (in a large sample) gave an "immune" reaction to vaccination, he regards this as strong evidence that such a reaction represents genuine immunity. But it has been known for many years that heated, inactivated vaccine virus can produce a papular reaction indistinguishable from that caused by live virus. This was well shown by Andervont and Rosenau,²⁶¹ and by MacKinnon and Defries²⁶² among many others, and has been recently confirmed.^{275 293 294} Benenson²⁹⁴ has carried this farther, showing that heated and unheated vaccine from the same batch can even produce identical vesicular reactions. Thus, it is not always possible to tell whether the result observed was caused by live or dead virus. Furthermore, he has shown that the production of a papular or vesicular lesion with heated virus is not ordinarily associated with a serologically demonstrable immune response. Using the complement-fixation test and the agglutinin-inhibition technic developed by Nagler,²⁹⁵ Benenson and Kempe²⁹⁶ have demonstrated that an early immune type of reaction produced by live

virus is generally accompanied by a rise in the subject's serum antibody titer, but that no such rise is observed if heated virus is used. Benenson therefore believes—agreeing in this instance with Mitman⁷⁶—that a reaction to vaccination that reaches its height within seventy-two hours is quite literally uninterpretable. If this proves to be the case, an early reaction can no longer be regarded as evidence of successful revaccination, and the vaccinator must depend for success, in such cases, entirely upon proper technic and the assurance of a supply of fresh potent vaccine. Thus it again becomes evident that successful revaccination depends very largely upon observance of the expiration date on each package of vaccine, and also upon the utmost diligence in keeping the vaccine frozen when it is not actually in use or transit.

Little help has been offered by way of varying the route of administration of smallpox vaccine. A recent report from Finland indicates that long-term immunity in 369 cases following subcutaneous vaccination was lower than that produced by scarification.²⁹⁷

Technic of Preparing Vaccine

It is still commonly stated²⁹⁸ that sterile—that is, bacteria-free—smallpox vaccine cannot be produced in calves. Numerous workers have reported the use of penicillin to reduce the bacterial count in such vaccine. Equally striking results can be obtained, however, by the use of a quaternary ammonium detergent, such as "roccal," during incubation of the virus and while the vaccine is being harvested from the animal used.²⁹⁹ The effectiveness of this method has been amply confirmed by Dr J. A. McComb at the Massachusetts Antitoxin and Vaccine Laboratory, where bacteria-free preparations of ample potency have been repeatedly obtained. Many other institutions have assuredly done likewise.

Smallpox vaccine produced in fertile hen's eggs has not received wide acceptance as yet, but it has been in general distribution in Texas for several years. Of 779,250 doses distributed in that state, reports were obtained on 125,892 vaccinations, 87.3 per cent of which gave primary, accelerated or "immune" reactions. In a group of 39 persons vaccinated with chick-embryo vaccine one to five years previously, revaccination with calf vaccine gave 35 immune and 4 accelerated reactions. Thus, the duration of immunity produced by egg vaccine appears to be within normal limits. The egg vaccine was reported to have caused milder local reactions, smaller vesicles, less secondary infection and less systemic disturbance than the standard calf vaccine.³⁰⁰ However, until egg vaccine has been shown to be effective in stopping a smallpox epidemic, it will apparently not be generally accepted by health authorities, since the merits of calf vaccine in this respect are already well established.

of its occurrence in presumably vaccinated persons, was vividly described a year ago by Agerty,²⁵⁹ who observed 17 cases with 10 deaths among American personnel in Japan. Only 4 of these patients had histories or scars indicating that they had been vaccinated in childhood. All but 3 had been recorded as having been vaccinated within the preceding two years, in 2 vaccinoid reactions had developed, the other 12 being noted as "immune," "doubtful" or "unsuccessful." (The probable significance of "immune" reactions is discussed below.) Reports from other sources have indicated scattered failures to protect American personnel in the Orient by the use of the standard vaccination procedure and the vaccine available at the time. Hence it was not surprising that cases appeared among servicemen returning to the West Coast. Such cases caused a small outbreak in San Francisco early in 1946,²⁶⁰ and a much larger one in and around Seattle.^{261, 262} The latter outbreak produced at least 65 cases with 20 deaths (a 30.8 per cent case mortality) and took four months to stamp out. An incidental result of this outbreak was an unprecedentedly successful vaccination campaign in neighboring British Columbia, which probably reached 250,000 people. This may be contrasted with the 80,000 in the province who submitted to vaccination fourteen years earlier in the presence of an actual smallpox outbreak. Apparently, the public at large has become widely educated, in the interval, regarding the wisdom of being vaccinated.²⁶³

If proof of this acceptance of vaccination were needed, the New York City outbreak of March-April 1947 has furnished it. A total of 8 confirmed cases in New York City, and 4 outside the city, occurred over a period of about six weeks. The findings in most of these cases have been thoroughly expounded and discussed in a clinicopathological conference.²⁶⁴ The first case was atypical and not recognized until secondary cases were diagnosed, by which time it was evident that numerous scattered tertiary cases might be expected to appear. The decision was therefore made to vaccinate the entire city. Over 6,000,000 people were actually vaccinated during the following two weeks.²⁶⁵ This was accomplished by extraordinary efforts on the part of local medical and health personnel and also of the producing firms, which were faced with a demand for vaccine unparalleled both in size and in urgency. This outbreak caused widespread alarm elsewhere, increases in vaccination demands being observed at least as far away as Michigan. Although states such as Massachusetts and Michigan, having their own production facilities, were able — with difficulty — to keep pace with the demand, many other communities saw their supplies of vaccine temporarily exhausted. The experiences of the last two years suggest that it is entirely possible for several virulent foci of smallpox to be established in this country at about the same time. In

such an event, vaccine supplies would certainly be temporarily inadequate. This possibility focuses attention on the importance of maintaining a large immune population, by vaccination in infancy and periodic revaccination.²⁶⁶ This is clearly demonstrated by the New York experience, which showed that perhaps 50 per cent of the people in that urban area were susceptible to infection, as indicated by either a primary or a vaccinoid reaction.⁵

England has had similar but considerably more numerous experiences, as indicated in several excellent reports of outbreaks of virulent smallpox in that country.^{267, 272} Mortality rates have been high — for example, 3 deaths in 11 cases,²⁶⁸ 9 in 31 cases,²⁶⁹ and 6 in 30 cases.²⁷¹ Control has been difficult owing to unfamiliarity of local physicians with the diagnosis, to the high level of susceptibility in England, where compulsory vaccination has always been resisted and in fact has recently been abandoned,²⁷³ and to the marked and prolonged contagiousness of infected materials, smallpox crusts sometimes remaining infectious for as long as a year.²⁷⁴

Interpretation of Vaccination Reactions

Complications

Eczema vaccinatum continues to occur occasionally here³⁰¹ and elsewhere in eczematous children who are permitted, through ignorance or error, to come in contact with recently vaccinated persons. Such patients still occasionally die,²⁹⁸ very much more rarely than before chemotherapeutic agents were available and modern knowledge of the care of such patients was developed. Two deaths were observed among 36 cases arising in conjunction with the mass vaccination of 6,000,000 people in New York City last year.⁶ Excellent descriptions of 16 of these cases, with a review of the pertinent literature, have recently appeared.³⁰² Fifteen other cases in the same outbreak have been described separately.³⁰³

Post-vaccinal encephalitis remains, in this area, a very rare complication. Even cases reported as such are not always correctly diagnosed. Cavaillon et al.³⁰⁴ report that, among over 1,000,000 vaccinations in the Paris area after a recent smallpox outbreak, notifications of 2 cases of "post-vaccinal encephalitis" were given, on post-mortem examination, however, death was found in both to have been due to bronchopneumonia. An analogous instance occurred in Boston a few years ago. In some countries, however, true post-vaccinal encephalitis occurs in sporadic outbursts of puzzling nature and localization. In and around Basel, 6 cases occurred among 30,000 vaccinations in the urban district in 1945, and 9 more occurred in the rural environs, whereas in Berne no cases occurred among 100,000 vaccinations.³⁰⁵ In a very comprehensive summary of reports of this disease from all parts of the world, Stuart³⁰⁶ notes case incidences ranging from 1 per 641 vaccinations (Tyrol, 1929) to none in over 1,000,000 (France, 1923-1928, and Italy, 1927). The evidence is clear that this complication is persistently recurrent in some areas, and virtually nonexistent in others, without relation to the source of the vaccine used, the manner of use or any other known technical factor. All reports agree that the incidence is far less in infants under three years of age than in older subjects^{300, 306}, it appears also to be rarer after revaccination, although 26 cases following revaccination have been observed in Holland.³⁰⁶ The limited experience in treating post-vaccinal encephalitis with convalescent serum — chiefly in England — is equivocal, 8 of 14 treated patients from 1940 to 1945, inclusive, recovered as against 21 recoveries in 44 untreated cases.³⁰⁷ There is a fifty-fifty chance that this difference was accidental.

To the collection of miscellaneous and bizarre reactions to vaccination there has been added a report from England of a high incidence of evanescent photosensitization rashes resulting from the combined effects of sulfanilamide, sunshine and vaccination. Rashes did not appear in persons in

whom vaccination had failed or been refused. The mechanism of the reaction remains unexplained.³⁰⁸

Many thoughtful investigators have considered the possibility that vaccination might cause abortion or fetal malformation in a pregnant woman. During the recent city-wide vaccination program in New York City, Bellows, Hyman and Merritt¹⁴³ observed the effect of vaccination on pregnancy in a series of 720 vaccinated women and 173 controls. No significant differences were demonstrated between the vaccinated and control groups in the incidence of malformation, stillbirth, abortion or infant deaths.

(To be concluded)

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35281

PRESENTATION OF CASE

A forty-seven-year-old housewife was admitted to the hospital complaining of abdominal swelling.

Thirteen years before admission, following the birth of normal twins, the patient developed a post-partum psychosis with hallucinations. She was in a mental hospital for about two years, but improvement was incomplete. At home, during the subsequent decade, she remained mentally disturbed, but tended the house. Her appetite was always very poor, and her diet was fair with few eggs and rare fish and meat. Her menses were normal until fifteen months before admission, when amenorrhea and hot flashes appeared. Subse-

quently she felt increasing fatigue, anorexia and weight loss, with intermittent numbness and tingling in her feet. Her physician prescribed vitamins and administered liver injections, without improvement. The symptoms increased in severity during the year before admission. Her legs and hands had occasional episodes of tingling. In the month before admission she noted weakness of her legs on walking and climbed stairs with difficulty. In the few months just before admission she also noted that her legs had a tendency to develop ecchymosis easily on trauma, and she had occasional retching in the morning. For six months before admission, she consumed 5 or 6 ounces of whiskey and a bottle of beer daily in the hope that her appetite would be stimulated. There was no favorable response, however, and she ate about a fourth of a normal food portion. Ten days before admission, she developed watery diarrhea, which cleared up in two days. She felt weak, and one week before admission noted that her abdomen was swelling, and that there was mild ankle edema. She went to bed. Two days later her eyes were yellow, and her urine dark brown. No abnormality in the stools was noted. Abdominal swelling increased in the few days before admission.

She had never been jaundiced before, and had not been exposed to other jaundiced people. There was no history of gall-bladder disease.

Physical examination showed a thin, tremulous, icteric woman with a mousy odor to her breath. Her abdomen was tense and distended, and shifting flank dullness was present. There were no periumbilical dilated veins. The liver was enlarged to midway between the costal margin and umbilicus.

The edge was very firm. The spleen was not palpable.

The blood pressure was 90 systolic, 65 diastolic. The temperature was 99°F, the pulse 100, and the respirations 20.

Examination of the blood showed a white-cell count of 26,000, with 79 per cent neutrophils, 12 per cent lymphocytes, 5 per cent monocytes, 3 per cent eosinophils and 1 per cent basophils. The hemoglobin was 11 gm. The urine was dark amber, with a specific gravity of 1.013 and gave a +++ test for bile. The stools were soft brown and guaiac negative. The alkaline phosphatase was 21 units, the nonprotein nitrogen 18 mg, the albumin 2.85 gm, and the globulin 2.69 gm per 100 cc. The cholesterol was 180 mg per 100 cc, and the sodium 125.2 milliequiv and the chloride 78 milliequiv per liter. The van den Bergh reaction was 5.6 mg per 100 cc direct and 7.2 mg indirect, and the cephalin-flocculation test was ++ in forty-eight hours. The prothrombin time was 23 seconds (control, 15 seconds).

On x-ray examination the findings in the chest were not unusual, and the findings in the esophagus were suggestive but not diagnostic of varices.

On the second hospital day an abdominal paracentesis yielded 2100 cc of slightly greenish fluid, with a specific gravity of 1.008 and 130 red cells and 20 lymphocytes per cubic millimeter. The patient did poorly. On the third hospital day alimentation with Levine-tube feedings was instituted. She became disoriented, and then unresponsive. The icterus did not increase, but ascites rapidly reaccumulated. The temperature rose to 102°F, and the white-cell count reached 40,000.

The patient's condition continued to deteriorate, and she died on the ninth hospital day.

DIFFERENTIAL DIAGNOSIS

DR C W FAIRLIE: When a woman enters the hospital with a history of ascites and jaundice for one week and dies within nine days, we have to assume that she died from liver disease. The questions are, What kind of liver disease and what precipitated this rapid demise? The first thought that comes to mind with so rapid a fatality is acute yellow atrophy or acute necrosis, but I do not believe that the patient had this condition. I think, rather, that she had a long-standing cirrhosis with some catastrophe superimposed that caused the final decline.

I will review the history in search of clues toward this conclusion. The mental illness I can make nothing of except that it contributed to her having apparently a subnormal diet over a period of ten or more years. The amenorrhea appeared just at the onset of her symptoms, fifteen months before admission. Since it was accompanied by hot flashes, I doubt that it was amenorrhea due to debilitating disease but rather was the menopause

appearing at the age of forty-seven. The symptoms of anorexia, fatigue and weight loss for fifteen months are common in cirrhosis, but they are frequent in other conditions. The tingling and numbness in her legs suggest peripheral neuritis, but this was never confirmed by other evidence. The alcohol intake is not noted until the mention of its use as an appetizer for six months before entry, but one who turns to this amount of appetizer and continues it even though it is not helping has probably enjoyed the medicine before. Diarrhea was noted ten days before admission and did not recur. A mousy odor to the breath is mentioned. Interpretation of this finding is difficult from the printed word or, indeed, from examining the patient. The liver was enlarged to midway between the costal margin and the umbilicus, and the edge was firm. That is an important observation and would be most unlikely in a patient about to die, nine days later, from acute yellow atrophy of the liver.

The white-cell count of 26,000, and later of 40,000, must be a clue to the underlying process, but not a very specific one. It can occur in acute necrosis of the liver. However, it could also occur with infection or with severe hemorrhage. The phosphatase of 21 Bodansky units per 100 cc is higher than that usually seen with parenchymal liver disease but such exceptions are becoming increasingly familiar. Regarding the albumin and the globulin, it is a pleasure to see them stated as such with no reference to the ratio obtained by dividing these two unrelated quantities one into the other. The low albumin is suggestive of long-standing liver disease but could occur with acute hepatitis or acute necrosis also. The sodium of 125 milliequiv per liter, together with the blood pressure of 90 systolic, 50 diastolic, forces one to mention Addison's disease, but there is nothing else to go with it and I think this electrolyte depletion was merely a part of the acute liver failure.

I would like to see the x-ray films particularly to discover whether the line of the right leaf of the diaphragm is smooth and how much evidence there is for esophageal varices.

DR JOSEPH HANELIN: I think the chest is essentially normal. The right side of the diaphragm is not unusual in appearance. The lungs appear clear. The heart is not enlarged. We have a single spot film of the barium-filled esophagus, and there are definitely wide folds, with undulating contours that strongly suggest varices. I do not know whether there are other films that are more suggestive, but this is almost diagnostic of varices.

DR FAIRLIE: That is strong support for the assumption that she had long-standing liver disease rather than only an acute process—an assumption that is strengthened by the initiation of the final episode with jaundice and ascites but without other symptoms, she was not apparently acutely ill in

other respects. That would be unusual for acute yellow atrophy. The liver was large and very firm, which would likewise be unusual. Further support for the presence of long-standing liver disease is found in the fifteen months' history of nonspecific symptoms and the history of poor nutrition, probable alcoholism and probable esophageal varices.

We thus come to the conclusion that she had portal cirrhosis. What, then, caused her sudden decline? One of the common phenomena that cause cirrhotic patients to become decompensated is infection. This can be an infection of any kind. Even a brief episode of gastroenteritis can be responsible. The white-cell count suggests infection in this patient, but there were no localizing signs. I suppose it could have been a hidden infection, such as mediastinitis, or a deep phlebitis. But there is no reason to think of such entities except that we are searching for infection. Under the heading of infection should be mentioned viral hepatitis. It is uncertain how large a part viral infection of the liver plays in the course of chronic liver disease due to other conditions.

Another common incident precipitating hepatic failure in cirrhotic patients is hemorrhage. It is familiar to see such a patient with acute blood loss shortly thereafter become jaundiced and develop ascites. However, in this patient the stools were guaiac negative, the ascitic fluid was not bloody, and the hemoglobin was 11 gm per 100 cc. Hence I will dismiss this possibility.

A final consideration, and the one that I think is most likely, is thrombosis of the portal or hepatic veins or possibly of the vena cava. This could account for the sudden development of ascites and jaundice and for the high white-cell count and likewise for the rapid death. Such a thrombosis is sometimes caused by a hepatoma encroaching on the lumen of the vessels. There is little on which to base such a supposition in this case.

I will conclude that the patient had portal cirrhosis. I do not believe the episode leading to her death in hepatic failure was an acute yellow atrophy. The precipitating incident may have been thrombosis of the hepatic portal vein.

DR DONALD S. KING: I saw this patient in the wards for several days before she died. My opinion was that autopsy would show some areas of acute necrosis in the liver in spite of the fact that it was enlarged and apparently hard. I notice that the house officer also suggested that thrombosis would be found at autopsy. We had not thought much about that on the ward. We tried to explain the fever and high white-cell count and diarrhea. We were surprised at the gross autopsy findings, although I do not know what the microscopical findings were.

DR JOHN HOGAN: Have you seen this electrolyte disturbance in cases of liver disease frequently? The patient was not on salt restriction.

DR FAIRLIE: The numerous cases that came to mind have been the result of therapy, but in a patient with an inadequate diet I believe it could occur even without strict limitation of sodium intake.

CLINICAL DIAGNOSES

Laennec's cirrhosis, ? hepatoma of liver
Cholemia

Thrombosis of portal or hepatic vein?

DR FAIRLIE'S DIAGNOSES

Portal cirrhosis

Thrombosis of portal or hepatic vein

ANATOMICAL DIAGNOSES

Cirrhosis of liver, alcoholic type, acutely progressive

Hyperplasia of bone marrow, marked

Extramedullary hematopoiesis, spleen

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: Autopsy showed a large, firm, pale and fatty liver, which at first glance seemed smooth but which, when viewed with oblique lighting, could be seen to be finely granular. It cut with resistance, however, and was obviously much tougher than normal. The spleen was only slightly enlarged, weighing 200 gm., and esophageal varices were questionable in our opinion, although I think the x-ray verdict is probably more accurate than ours, since we only see the specimens in the collapsed state. There was nothing else in the gross examination that was particularly remarkable, except the adrenal glands, which were quite swollen, and the bronchi, which contained some purulent exudate.

Microscopical examination of the liver showed a very acutely progressive cirrhosis of the type that we commonly see in alcoholic patients, with moderate amounts of fat and slight diffuse fibrosis, but with a great many cells showing hyaline degeneration and a very unusual degree of infiltration of the liver with polymorphonuclear leukocytes, particularly in the portal areas and about the degenerating liver cells. I would describe it as an alcoholic cirrhosis progressing almost at a fulminating rate—as marked as I have ever seen.

One other surprise was provided by microscopical examination of the bone marrow and spleen. The bone marrow was intensely hyperplastic, with hyperplasia of the red-cell series and quite a considerable proportion of rather primitive cells. It was slightly suggestive of what one sees in pernicious anemia. The spleen also was full of foci of hematopoiesis. I do not know of any certain way of connecting the liver disease and the bone-marrow findings and am inclined to think that the bone marrow was another evidence of dietary deficiency in this patient, rather than being due to the liver condition.

DR BENJAMIN CASTLEMAN We have had several patients with so-called acute alcoholic cirrhosis with white-cell counts of 40,000

DR MALLORY Yes, the count can run very high I do not think we have seen a bone marrow as active as this, and never extramedullary hematopoiesis

DR MADELAINE BROWN I do not suppose you removed a peripheral nerve, did you?

DR MALLORY Yes, we did, but the neuropathologist has not yet reported upon it

DR HOGAN The adrenal glands were normal microscopically?

DR MALLORY There was lipoid depletion and swelling of the pseudotubular type It is a non-specific type of response that one sees in most infectious diseases, as well as in a great variety of noninfective diseases

CASE 35282

PRESENTATION OF CASE

A forty-eight-year-old man entered the hospital complaining of headache and intermittent vomiting for two weeks (The history was obtained from the patient's wife because he was drowsy)

Three and a half weeks before admission he sprayed his apple orchard with a mixture of lead arsenate and DDT, about 35 gallons were used Three weeks before admission he had an occipital headache, which lasted two days and was relieved by aspirin A few days later he again sprayed the trees with the same mixture The spray nozzle broke, and the patient was drenched with the solution He changed his clothes and finished his work Two weeks before admission the occipital headache recurred and was more severe On the following day he started vomiting in a projectile fashion His doctor found him afebrile, with a strong, slow pulse Urinalysis showed a few red blood cells The occipital headache continued, and the patient became lethargic, sleeping most of the time Ten days before admission he complained of dizziness and weakness on trying to get out of bed and inability to see well without his glasses Three days later he was admitted to another hospital, where the general physical examination demonstrated no abnormalities Positive neurologic findings included moderate weakness in the grip of the right hand and weakness of the right leg, but there was no wrist or foot drop The right knee jerk was greater than the left The blood pressure was 128 systolic, 80 diastolic, and the pulse 68 The red-cell count was 5,000,000 on two examinations Two of three blood smears examined reported stippling in 1-400 and 1-500 cells Five days before admission he seemed irrational and could not answer questions or carry on conversation On the third and second days be-

fore admission he received BAL, and his symptoms cleared up slightly He was transferred to the Massachusetts General Hospital for further study

The patient had always been in excellent health until the onset of the present illness except for moderate deafness, present from the age of nineteen This had been treated recently with pyribenzamine, with some symptomatic relief

On admission the patient was drowsy and apathetic The general physical examination was negative except for a pilonidal sinus The initial neurologic examination demonstrated extreme nuchal rigidity, a negative Kernig sign, bilateral papilledema of two diopters and flaccid paralysis of the right arm and leg, with hypoactive right deep tendon reflexes and normal sensation

The temperature was 99°F, the pulse 90, and the respirations 18 The blood pressure was 122 systolic, 82 diastolic

Examination of the urine was negative, a test for arsenic was also negative Examination of the blood showed a white-cell count of 17,000, with 90 per cent neutrophils, 3 per cent lymphocytes, 6 per cent monocytes, and 1 per cent eosinophils Occasional stippling of the red cells was noted The hemoglobin was 14.5 gm Chemical examination of the blood demonstrated a non-protein nitrogen of 37 mg, a total protein of 6.6 gm, a calcium of 10.6 mg, a phosphorus of 4.5 mg and an alkaline phosphatase of 5 mg per 100 cc The chloride was 100 milliequiv per liter On lumbar puncture the initial spinal-fluid pressure was equivalent to 285 mm of water, and after 10 cc of clear, colorless fluid was removed it was equivalent to 95 mm of water The total white-cell count was 21 per cubic millimeter, with 7 lymphocytes and 14 polymorphonuclear leukocytes Globulin reaction was positive, and the sugar was 110 mg per 100 cc, the chloride 124 milliequiv per liter, and the total protein 84 mg per 100 cc The fluid was sterile

The patient was placed on BAL therapy, 250 mg 6 times a day intramuscularly, a high-calcium diet, calcium levalinate (1 amp intravenously three times a day for two days), syrup of sodium citrate (2 gm orally four times a day) and 1000 cc of 5 per cent dextrose and water For the first three hospital days the patient became more stuporous, drowsy and disoriented The speech became slurred, he responded to commands slowly and often inaccurately On the third day neurologic examination showed severe nuchal rigidity and left external rectus weakness, the left eye remaining almost in midposition when the right eye was markedly abducted The right hemiparesis was severe, involving the proximal as well as the distal muscles, with marked loss of tone and diminished reflexes No definite facial weakness or anesthesia and no gross sensory loss were detected

other respects. That would be unusual for acute yellow atrophy. The liver was large and very firm, which would likewise be unusual. Further support for the presence of long-standing liver disease is found in the fifteen months' history of nonspecific symptoms and the history of poor nutrition, probable alcoholism and probable esophageal varices.

We thus come to the conclusion that she had portal cirrhosis. What, then, caused her sudden decline? One of the common phenomena that cause cirrhotic patients to become decompensated is infection. This can be an infection of any kind. Even a brief episode of gastroenteritis can be responsible. The white-cell count suggests infection in this patient, but there were no localizing signs. I suppose it could have been a hidden infection, such as mediastinitis, or a deep phlebitis. But there is no reason to think of such entities except that we are searching for infection. Under the heading of infection should be mentioned viral hepatitis. It is uncertain how large a part viral infection of the liver plays in the course of chronic liver disease due to other conditions.

Another common incident precipitating hepatic failure in cirrhotic patients is hemorrhage. It is familiar to see such a patient with acute blood loss shortly thereafter become jaundiced and develop ascites. However, in this patient the stools were guaiac negative, the ascitic fluid was not bloody, and the hemoglobin was 11 gm per 100 cc. Hence I will dismiss this possibility.

A final consideration, and the one that I think is most likely, is thrombosis of the portal or hepatic veins or possibly of the vena cava. This could account for the sudden development of ascites and jaundice and for the high white-cell count and likewise for the rapid death. Such a thrombosis is sometimes caused by a hepatoma encroaching on the lumen of the vessels. There is little on which to base such a supposition in this case.

I will conclude that the patient had portal cirrhosis. I do not believe the episode leading to her death in hepatic failure was an acute yellow atrophy. The precipitating incident may have been thrombosis of the hepatic portal vein.

DR DONALD S. KING: I saw this patient in the wards for several days before she died. My opinion was that autopsy would show some areas of acute necrosis in the liver in spite of the fact that it was enlarged and apparently hard. I notice that the house officer also suggested that thrombosis would be found at autopsy. We had not thought much about that on the ward. We tried to explain the fever and high white-cell count and diarrhea. We were surprised at the gross autopsy findings, although I do not know what the microscopical findings were.

DR JOHN HOGAN: Have you seen this electrolyte disturbance in cases of liver disease frequently? The patient was not on salt restriction.

DR FAIRLIE: The numerous cases that came to mind have been the result of therapy, but in a patient with an inadequate diet I believe it could occur even without strict limitation of sodium intake.

CLINICAL DIAGNOSES

Laennec's cirrhosis, ? hepatoma of liver
Cholemia
Thrombosis of portal or hepatic vein?

DR FAIRLIE'S DIAGNOSES

Portal cirrhosis
Thrombosis of portal or hepatic vein

ANATOMICAL DIAGNOSES

Cirrhosis of liver, alcoholic type, acutely progressive
Hyperplasia of bone marrow, marked
Extramedullary hematopoiesis, spleen

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: Autopsy showed a large, firm, pale and fatty liver, which at first glance seemed smooth but which, when viewed with oblique lighting, could be seen to be finely granular. It cut with resistance, however, and was obviously much tougher than normal. The spleen was only slightly enlarged, weighing 200 gm., and esophageal varices were questionable in our opinion, although I think the x-ray verdict is probably more accurate than ours, since we only see the specimens in the collapsed state. There was nothing else in the gross examination that was particularly remarkable, except the adrenal glands, which were quite swollen, and the bronchi, which contained some purulent exudate.

Microscopical examination of the liver showed a very acutely progressive cirrhosis of the type that we commonly see in alcoholic patients, with moderate amounts of fat and slight diffuse fibrosis, but with a great many cells showing hyaline degeneration and a very unusual degree of infiltration of the liver with polymorphonuclear leukocytes, particularly in the portal areas and about the degenerating liver cells. I would describe it as an alcoholic cirrhosis progressing almost at a fulminating rate—as marked as I have ever seen.

One other surprise was provided by microscopical examination of the bone marrow and spleen. The bone marrow was intensely hyperplastic, with hyperplasia of the red-cell series and quite a considerable proportion of rather primitive cells. It was slightly suggestive of what one sees in pernicious anemia. The spleen also was full of foci of hematopoiesis. I do not know of any certain way of connecting the liver disease and the bone-marrow findings and am inclined to think that the bone marrow was another evidence of dietary deficiency in this patient, rather than being due to the liver condition.

In favor of a tumor of the brain he had had a repeated history of several weeks of progressive drowsiness, headache, choked disks and signs of increased intracranial pressure. There is one point about dealing with the spinal-fluid pressures, the Ayala index—I do not use this index very often, but it may help here. The quantity of fluid removed is multiplied by the final pressure, and the product is divided by the initial pressure. If the ratio is over 5, it is supposed to indicate a diffuse cerebral lesion, with increased spinal-fluid volume. When it is under 5 it is supposed to indicate a space-occupying lesion. With these spinal fluid findings— $\frac{10 \times 95}{285}$ —we have a low index, 3.3,

which goes with tumor, probably in the posterior fossa. The spinal-fluid protein of 84 gm per 100 cc and the positive globulin are consistent with tumor. The neurologic signs are interesting in that on the third day there was weakness of the left external rectus muscle and right hemiparesis, which suggest that the lesion was near the midbrain but outside it. The air studies suggest something displacing the aqueduct to the left and forward. I think that would be unusual in any poisoning. It suggests tumor in the posterior fossa with pressure in that region. The stiffness of the neck is also consistent with posterior-fossa tumor. Just before death the reduction in reflexes and the hyperthermia would also be associated with a posterior-fossa lesion. A tumor or an aneurysmal sac would be the two things that one would think of. It seems to me, therefore, that the weight of evidence is against poisoning, although I cannot explain the stippling. I should say that he had a lesion of the left posterior fossa near the midline. The x-ray evidence puts it on the other side, which would involve the pyramidal tract from the right hemisphere. Another point worth mentioning is that the seventh-nerve pyramidal fibers cross at the level of the third-nerve nucleus, which would be above the area involved by this lesion. Hemiplegia involving the arm and leg without involving the face is consistent with a posterior-fossa lesion of the left side.

A PHYSICIAN: Would you consider a secondary metastasis to the brain?

DR SCHWAB: Yes. The data indicated no primary source for the tumor, and the lungs were normal. When I said "tumor" I did not say what kind. It may have been a metastatic tumor. This was a fairly rapidly growing one, it could have been either.

DR WILLIAM H SWEET: On the ward a nice and lively discussion ensued in this case. From the ventriculograms I said that there was evidence of a space-taking lesion, on the right side of the

posterior fossa. Our neurologic colleagues thought that the clinical picture was not sufficiently suggestive of that and took the patient back on their service. I think this case is important to point out again that if one does a ventriculogram, and demonstrates by that procedure a probable neoplasm, there is often very little time remaining for a discussion. The patient must be taken promptly to the operating room, and the neoplasm, if present, treated immediately. In this case we consider that even if there had been a lead encephalopathy, proper treatment was a suboccipital craniectomy for decompression. In the lone case in my personal experience in which lead encephalopathy was so handled the outcome was satisfactory.

CLINICAL DIAGNOSIS

Tumor or abscess of brain

DR SCHWAB'S DIAGNOSIS

Tumor, left posterior fossa

ANATOMICAL DIAGNOSES

Carcinoma of ascending colon, with metastases to brain, liver, lung and lymph nodes

Arteriosclerosis, generalized, slight

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: Autopsy in this case showed something that would not be remotely suggested by the record. The patient had a primary cancer of the ascending colon, with widespread metastases throughout the body.

DR SCHWAB: Was there nothing in the lungs?

DR MALLORY: Multiple metastases were present in the lungs, which I think should have been demonstrated by x-ray examination. The liver was full of them. As far as the central nervous system is concerned, we found two tumors in the cerebellum—one in the right and one in the left hemisphere. There were two other intracerebral tumors, one in the left parietal and one in the right temporal lobe.

DR SCHWAB: The right temporal and left parietal metastases were apparently silent. Can you see anything in the chest, Dr Wyman?

DR WYMAN: I do not see any pulmonary metastases. It is interesting to point out that it is not uncommon to have extensive lesions that cannot be demonstrated on the films. Tuberculosis is certainly a common offender. Could the tumors have caused displacement of the lateral ventricles toward the right in the anteroposterior films?

DR MALLORY: I think they could have.

DR SCHWAB: Was that a large lesion in the parietal lobe?

DR MALLORY: No—slightly under 1 cm in diameter.

X-ray films of the skull, right hand and arm and a posteroanterior film of the chest were normal. An electroencephalogram showed a diffusely abnormal record, with moderately slow activity, a little more marked on the left than on the right side of the head, especially in the central and, to some extent, the parietal region. The temperature, pulse and respirations went up to 102°F, 130 and 28, respectively. A lumbar puncture on the same day showed an initial spinal-fluid pressure equivalent to 340 mm of water, with 12 polymorphonuclear leukocytes and 3 lymphocytes per cubic millimeter. The patient was started on penicillin, 100,000 units every three hours intramuscularly, and given 10,000 units of penicillin intrathecally at the time of the lumbar puncture. A ventriculogram on the fourth day showed slightly dilated lateral ventricles, a little more marked on the right. The third ventricle was slightly dilated. The aqueduct and fourth ventricle showed a slight shift to the left, and the aqueduct was also displaced slightly forward. During the day his condition became worse, with a return of rapid pulse to 140, a gradual rise in temperature to 103.6°F and a continued comatose condition.

At 5:30 p.m. that day he suddenly became cyanotic, with shallow breathing. Oxygen and artificial respiration were started. A ventricular tap showed clear spinal fluid under increased pressure. He died at 5:40 p.m.

DIFFERENTIAL DIAGNOSIS

DR. ROBERT S. SCHWAB: Did this man develop the occipital headache before or after the spraying episode, when the nozzle of the hose broke? I think that is an important question.

DR. WILLIAM H. SWEET: It occurred after the nozzle broke.

DR. SCHWAB: I should like to look at the x-ray films. Where is the pineal body?

DR. STANLEY M. WYMAN: I cannot demonstrate it on the anteroposterior or posteroanterior films. In the lateral film it appears to be approximately in the normal position.

DR. SCHWAB: I am interested in the statement that the aqueduct was displaced forward and to the left.

DR. WYMAN: The displacement of the aqueduct is best seen in this posteroanterior view. The third ventricle is dilated, lying close to the midline, the aqueduct extending a little toward the left. We filled part of the left ventricle, the right does not seem to fill. The displacement anteriorly is best seen in the occipital position, and the aqueduct can be seen starting horizontally and taking a sharp bend caudally, with a 90° angle at this point. The fourth ventricle is definitely filled. The distal portion of the aqueduct is displaced anteriorly and to the left.

DR. SCHWAB: Is the pineal body in normal position in spite of the displacement of the aqueduct?

DR. WYMAN: I cannot see any shift of the pineal body in the anteroposterior view.

DR. SCHWAB: The essential clinical findings in a man forty-eight years old with headache, projectile vomiting, stupor and hemiparesis at once suggest intracranial tumor. On the other hand the history given by his wife makes me think of poisoning from heavy metals or DDT. The differential diagnosis is therefore between poisoning from lead, arsenic or DDT, so-called toxic encephalopathy and tumor. In favor of the diagnosis of poisoning is the temporal relation of this unusual simultaneous exposure to arsenic, lead and DDT (in a 35-gallon amount) some three weeks before admission to the hospital. On the other hand, there is a clue in the statement that the headache in the occipital region came on before he was covered with liquid when the spray nozzle broke. It may be a false clue however. There are several points against poisoning. He was covered with liquid, but he took off his clothes and presumably washed himself so that there was no chronic exposure. He might not have swallowed any of the mixture. For the diagnosis is the report of a small amount of stippling, 1-500 only, on two smears. Outside these two items the picture is not characteristic of heavy metal poisoning. Against poisoning with metals is the fact that there were no urinary symptoms such as hematuria or albuminuria, which almost always occur in heavy-metal poisoning of the acute type. Also, there was no anemia and no gastrointestinal symptoms such as diarrhea, cramps, colic, nausea and anorexia. There were no skin findings and no lead line on the gums. Patients with arsenical poisoning have dark skin on the hands but no peripheral signs such as sensory loss and wrist drop, which are found with DDT poisoning. However, I have never seen such a case. The administration of BAL evidently failed to do anything because this man continued downhill rapidly and died in spite of medication for heavy-metal poisoning, which he got in large amounts, and in spite of alkalis in tremendous doses. The spinal fluid does not show evidence of meningitis, such as is associated with arsenical poisoning, in which the cells are usually over 100 per cubic millimeter. The stiff neck and the definite rigidity without a Kernig sign or cells in the spinal fluid make me think of a posterior-fossa lesion rather than a meningitis. Another important finding is that this patient was progressively drowsy with aphasia in the end from pressure but was not delirious and did not have convulsions, which are almost always seen in fatal cases of lead encephalopathy before the terminal stage is reached. We have a whole group of points against the diagnosis of heavy-metal or DDT poisoning.

But the main value of this study is its implication that the descent of the doctor to the level of the gangster can happen in any country. The embracement of the utilitarian philosophy of Hegel, with its corollary of euthanasia, has its counterpart in American society — Dr Alexander cites chapter and verse in the form of the attitude of a physician and a hospital toward patients with chronic degenerative disease, he emphasizes the discussion of sterility and euthanasia at a meeting

THE PROTECTION OF PERSONNEL ENGAGED IN ROENTGENOLOGY AND RADIOLOGY*

F T HUNTER, M D,† O E MERRILL, B E E,‡ J G TRUMP, D Sc,\$ AND L L ROBBINS, M D ¶

BOSTON AND CAMBRIDGE, MASSACHUSETTS

WITH recent evidence suggesting that radiologists have a higher death rate from leukemia than their colleagues,^{1,2} protection from the dangerous effects of radiation in the fields of diagnosis, therapy and research becomes a subject of increased importance. Currently, a total exposure dose of 0.3 r per week is the accepted limit of safety.³ But whether this limit is really safe,⁴ or, indeed, whether it has much meaning at all is open to challenge.

It should be apparent that ionizing radiant energy, capable of penetrating to the blood-forming organs, produces quite a different effect upon the body as a whole than radiation that is absorbed for the most part by the skin. This fundamental principle was correctly understood by Mutscheller,⁵ who realized that a long wave-length tolerance dosage did not apply in the shorter wave-length ranges, and called attention to the great length of time required for the accumulation of an injurious dosage of "hard" radiation, and to the long latent period before resulting changes are positively recognized.

In the field of medical radiology, knowledge of radiation hazards has remained particularly unsatisfactory because of the difficulty in making precise determinations of exposure sustained in various diagnostic technics, and because relatively little effort has thus far been made to correlate such continuously repeated exposures with the ultimate biologic response. For these reasons, a program has been undertaken at the Massachusetts General Hospital with the object of establishing a more quantitative basis for relating radiation exposure to morphologic changes in the peripheral blood, and of determining the value, if any, of the peripheral blood picture as an early index of bone-marrow injury.

It was recognized from the start that this study should correlate adequate recorded information on the quantity and quality of radiation received by personnel during routine procedures with progressive blood changes over long intervals. The present communication is therefore a preliminary one. It describes a film badge developed during the course of the investigation that gives quantitative information on both the exposure dose and its quality, presents the results of physical studies made on the direct and scattered radiation to which personnel may be exposed, discusses the significance of these data and comments briefly on some early results of monitoring.

Measurements have been made of the intensity and quality of direct-beam radiation, and of scattered radiation from a phantom irradiated under conditions similar to those present during fluoroscopy. Braestrup,⁷ it is true, has pointed out that "Masonite pressdwood" phantoms are rather inaccurate for measurements of radiation below 200 kvp, but inasmuch as it was considered unwise to expose a particular patient long enough for certain determinations to be made, it seemed advisable to use this convenient material.

The present study has shown that, contrary to generally recorded opinion,⁸ the 90° scattered radiation from a phantom subjected to fluoroscopic radiation is actually more penetrating than the direct beam that produces it. This important but hitherto unappreciated fact has the following physical explanation. The phantom subjected to radiation produced at 50 to 140 kvp behaves as a filter and absorbs most of the "softer" components of the heterogeneous beams. Those scattered x-rays capable of emerging from the depth of such a phantom would be produced chiefly by the Compton-scattering process. Compton-scattered photons, however, are increased in wave length by only 0.024 Ångstrom unit for 90° scattering. This relatively small increase in wave length has little effect on the quality of the more penetrating components of the original beam, the softer components of which have been largely eliminated by absorption. As a result, the total scattered radiation,

NOTES FROM THE MEDICAL EXAMINER IDENTIFICATION OF BLOODSTAINS—I

There are few types of evidence that occur with greater regularity at the scenes of crimes of violence and bear implications of greater evidential importance than bloodstains Their recognition and characterization serve to localize the scene of the crime, aid in determining the manner in which it was committed and, if circumstances are favorable, help to identify the perpetrator It is therefore valuable to review current methods of blood identification and their application to legal medicine

The most sensitive tests for blood are those which make use of its catalytic activity in enhancing the oxidation of certain phenols and amines by hydrogen peroxide These reactions, which the benzidine, guaiac and phenolphthalein tests¹⁻³ exemplify, depend upon the blood peroxidase activity, an enzymatic function of the heme portion of the hemoglobin molecule The reactions are extremely sensitive Thin, invisible dried smears, caused by as little as 1 part of blood in 10,000 parts of water, may be detected by the benzidine test,* for example Even garments that have been laundered several times may yield evidence of previous bloodstains

Unfortunately, no one of these tests is by itself specific for blood Vegetable peroxidases, such as those present in horseradish, potato and turnip, cause similar reactions and may be destroyed by boiling, whereas the peroxidase activity of blood is relatively stable But the virtue of the catalytic blood tests, of which the benzidine test is the most generally practical for medicolegal purposes, rests in their high sensitivity and simplicity They are best used for screening purposes, not for proof If the test is negative, blood is absent, if it is positive, blood is suspected The following case provides an example to illustrate the point

A 64-year-old retired businessman, his wife and her elderly sister, who lived in a single house in a residential suburb,

*The benzidine reagent consists of 0.1 gm of benzidine and 0.2 gm of sodium perborate dissolved in 10 cc of 50 per cent acetic acid. It should be prepared immediately before use. An instantaneous blue color indicates blood

had not been seen for several days The apprehension of neighbors having been aroused, the house was entered through a window The 2 women were found in bed beaten to death, and the man hanging by a rope around the neck in the cellar The extent of blood splashes at the scene of the death of the women indicated that their assailant had been blood splattered The man was clean and dressed in a lounging robe and fresh pajamas Benzidine tests of the hands and body of the man revealed abundant evidence of washed blood The wash basin in the bathroom also revealed invisible blood stains The evidence substantiated the fact that the man had committed suicide by hanging after murdering the women

Bloodstains remain detectable on the hands, arms and body of a living person for several days, in spite of ordinary careful washing This fact is of considerable importance in the examination of suspects in murder cases, sex offenses and other bloody crimes of violence The reagent may be applied directly to the skin, or the skin may be swabbed by moistened filter paper, to which the reagent is then applied In examination of a person for bloodstains, it is important to keep in mind the possibility of local stains (without criminal implication) arising from chapped hands or lips, pimples, minor cuts and abrasions

For medicolegal purposes it is desirable to establish the presence of blood with greater certainty than can be done by the catalytic tests Spectroscopic examination and microcrystal tests add confirmatory, and frequently conclusive, evidence Because the spectroscopic examination requires relatively large amounts of blood, it is not applied so frequently as the microcrystal tests The Bertrand⁴ modification of the hemin crystal test[†] and the hemochromogen crystal test[‡] are applicable to any blood particle or stain that can be seen by the naked eye Each test may be carried out on a microscope slide, the resulting crystals being examined under the microscope In favorable cases the characteristic spectral absorption of the hemochromogen crystals may be confirmed by the use of a microspectroscope

†Reagent 1 gm of magnesium chloride 1 cc. of water, 5 cc. of glycine and 20 cc of glacial acetic acid A drop of reagent is added to the blood particle on a microscope slide and covered with cover slip and heated gently, nearly to boiling It is cooled reheated and then cooled and examined under low power Brown rhombic plates of hemin are observed.

‡Reagent 6 cc 10 per cent sodium hydroxide 6 cc. of pyridine 6 cc of saturated solution glucose and 14 cc of water The reagent improves with age and then deteriorates One drop is added to the blood particle on a microscope slide and a cover slip is applied The slide may be warmed very gently to induce crystal formation Characteristic, salmon pink, nearly rhombic plates occur

(Notices on page xi)

Over an exposure range between 0.005 and 0.14 r for a given radiation quality the net film density, D , beneath any one of the four "windows" was found to be a linear function of the exposure r , as measured in roentgens by an ionization chamber. Thus

$$rk = D \quad (1)$$

where k is a constant determined by both the filter and the film emulsion employed.

Moreover, each filter transmits monochromatic radiation in accordance with the equation

$$r/r_0 = e^{-\mu x} \quad (2)$$

where r_0 and r are the initial and final values, x is the thickness of the filter in cm, μ is the absorption coefficient of the particular material and e is the base of natural logarithms. And since an equation of similar form describes the absorption of a heterogeneous beam of radiation, such a beam of rays may be represented by a single "effective" wave length on which the filter produces equivalent attenuation.

The relations in equations (1) and (2) may therefore be applied to the film densities produced under the aluminum and steel filters. Since the incident radiation r_0 is the same for both filters we find that

$$\log D_a/D_s = \mu_s x_s - \mu_a x_a \quad (3)$$

where the subscripts denote aluminum or steel.

For filters of fixed thickness the difference between the two terms on the right-hand side of equation (3) in spectral regions with no absorption discontinuity is determined by the wave length in the case of monochromatic radiation, or by the "effective" wave length in the case of a heterogeneous beam. Hence the log ratio of the film density beneath any pair of "windows" — for example, aluminum and steel — is a measure of the quality of radiation and is independent of the quantity. The quality of the radiation used in this study has been specified both in terms of the log of the film-density ratio under the aluminum and steel windows ($\log D_a/D_s$) and in the conventional form of half-value layer (hvl) of aluminum.

Advantages of film badges. Study was made of the comparative value of pocket ionization chambers and filtered film badges for measuring the radiation received by personnel over a period of two weeks. This led to the selection of film badges for the following reasons:

The use of an open "window" and three metal filters permits an adequate determination of radiation exposure and quality on a single film.

With a photoelectric spectrophotometer capable of isolating a narrow wave-band width (140 Å at 5600 Å), reproducibility of film-density readings was found to be 2 per cent or better.

Stock dental films (Du Pont No. 550) thus exposed to diagnostic x-rays are capable of giving a measurable indication of heavy radiation exposure and, in the exposure-range of greatest interest (0.01 r to 0.14 r), show a linear relation between film density and total roentgens received.

By means of special sensitive films (Du Pont No. 552) exposure to kilovoltages above 200 and to gamma radiation can be similarly quantitated.

Unlike ionization-chamber electrometers, dental films are less subject to individual variations in sensitivity and do not give rise to errors from electrical leakage.

The film badge is more conveniently worn, and the developed film furnishes a permanent record.

Disadvantages of film badges. Film badges are inconvenient in two respects: fresh standards must be made whenever a new film emulsion is used, and

FIGURE 2 Quality Measured by Film Badges ($\log D_a/D_s$) 1-mm Aluminum Filtration

a, b, c = direct beam with different film emulsions, c' = side scatter with film emulsion the same as c

they must be prepared by exposure to the particular type of radiation to be measured. Figure 2 shows $\log D_a/D_s$ values for three different film emulsions obtained in the direct beam 8 feet from the target at kilovoltages of 50, 70 and 90, and with a filtration of 1.0 mm of aluminum. As these curves show neither parallelism nor consistent differences, it

though greatly reduced in intensity, has its average wave length shifted closer to the minimum wave length of the direct beam. Such scattered radiation must therefore be regarded as capable of reaching the blood-forming organs of the examiner in significant amounts.

Figure 1 (calculated from Ulrey⁹) shows the attenuation of intensity and the displacement of the average wave length of the 50 kvp tungsten spectrum toward the shorter wave-length region

FIGURE 1 The 50 Kvp Tungsten Spectrum

Attenuation of intensity and displacement of the average wave length toward the shorter wave-length region by filtration (modified from Ulrey⁹)

by filters of 10 mm of paper (carbon), 10 mm of aluminum, and by the steel-aluminum "window" of the film badge described below. These curves clearly illustrate how selective absorption of the "softer" components results in radiation with a "harder" average quality than that of the original heterogeneous beam.

MEASUREMENT BY IONIZATION CHAMBERS AND FILM BADGES

Ionization Chambers

Comparative studies were made of the suitability of several types of ionization chambers for intensity measurements in the kilovoltage range from 50 to 140. It was recognized that for the lower

voltages care must be taken to avoid excessive wall thickness, not only because of the softness of the radiation but also since the reading would be relatively more dependent on the atomic constituents of the "air-wall" material.

The instruments eventually used were Victoreen chambers of 250r and 0.25r capacity and two 0.2r full-scale pocket electrometers of the minometer type. Because eight minometers in test exposures showed rather large variations in individual sensitivity, two that gave the most consistent readings were employed in all the experiments. It was found that the 0.25r Victoreen chamber and this pair of minometers gave equivalent readings for 70 kvp and above. But in the region below 70 kvp, the minometer chambers showed advantages, presumably because of the thinner wall of the thimble. Finally, to reduce measurement errors to a minimum, in most of the experiments film badges and one or both types of ionization chambers were exposed simultaneously to the radiation.

Film Badges

Film-badge characteristics. To distinguish between the wide range of wave lengths characteristic of diagnostic roentgenology and therapeutic radiology, a film badge, similar in some respects to the one used by Braestrup,¹⁰ was provided with four filters or "windows." After a number of trials the following filters proved satisfactory: 1.015 mm (0.040") cadmium, 0.254 mm (0.010") tool steel plus 0.762 mm (0.030") aluminum*, 1.015 mm (0.040") aluminum, and an open "window." In order to prevent rusting, the steel filter was "gun-metalled" by treatment with ammonium polysulfide. Small holes drilled through one end of the cadmium filter were spatially arranged to form a code number. Before removal of the film for development, the remainder of the badge could be covered with lead, and the code number recorded for identification purposes on the film beneath the cadmium window with low-voltage x-ray.

In processing films, remarkably consistent results were obtained when the following technique was meticulously carried out. A fresh solution is made each time a series of films with unexposed controls is to be developed. A 1-gallon-size can of Eastman rapid-developing powder is dissolved in 2 gallons of water in a glass jar. When the solution has been stirred well and the temperature adjusted to exactly 68°F, the films are developed for exactly six minutes, being agitated once or twice meanwhile. After being rinsed the films are placed in hypo for ten minutes, and then they are washed for twenty minutes and dried. (After the films had been placed in the hypo, it was found the light should not be turned on until two minutes had elapsed.) Calibration against an r-meter must be made for each film-emulsion lot-number.

*Henceforth this filter is referred to as the steel filter.

QUALITY MEASUREMENTS WITH FILM BADGES OF
SIDE SCATTER BETWEEN 50 AND 90 KVP

Early in the study it became evident that x-ray quality as measured by film badges ($\log D_a/D_s$) was considerably "harder" for 90° scatter from the phantom (point C) than for the direct beam itself. This is illustrated in Figure 2 in which c is a $\log D_a/D_s$ curve for the direct beam at 50, 70 and 90 kvp, and c' is the corresponding one for side scatter at 50 and 84 kvp — both sets of measurements being made with films of the same emulsion number. Under the open "window," on the other hand, the net film density for the same r value at these different voltages was practically unchanged, whereas $\log D_a/D_s$ decreased as the kvp rose. Hence, in monitoring, total r received could be determined from the open "window" density, and the quality from the log ratio of the aluminum and steel densities.

Observations were also made on the quality of scatter at different positions lateral to the phantom, namely, 7.5 and 12.5 cm toward the side of the table, 7.5, 9.0 and 12.5 cm toward the foot of the table, and at the Bucky slot after removal of the phantom. With a 20-by-20-cm field, filtration of 1.67 mm of aluminum, and 84 kvp, quality as determined by $\log D_a/D_s$ values was relatively the same for all points enumerated.

EFFECT OF FIELD SIZE ON INTENSITY AND QUALITY
OF SIDE SCATTER

The factors used in making the following measurements were 85 kvp, 4 ma and 1.67 mm of aluminum filtration. Figure 4 shows the results of varying the field size. When the center of a square field coincides with the center of the phantom (C'), side-scatter intensity increases with the area of the field (the square of the field dimension). However, when the margin of a square field is kept at a fixed distance within and close to (2.5 cm) the phantom edge (C), intensity, while initially much greater, increases somewhat less than linearly with the field dimension. These findings are in accord with measurements made by Cilley, Leddy and Kirklin,¹² who have emphasized the protective value of maintaining at all times a minimal field size.

In contrast to these intensity variations, there is no change in side-scatter quality, as measured by film badges, when the centered field (C') is increased from 10 by 10 to 20 by 20 cm. Moreover, the quality of scatter from the 15-by-15-cm field is the same either centered (C') or near the phantom edge (C). As pointed out below, this side scatter is quite "hard," and has a half-value layer of 5.9 mm of aluminum. It is therefore more important than ever to keep the field size as small as possible when a patient is being fluoroscoped.

COMPARATIVE STUDIES OF DIRECT BEAM AND 90°
SIDE SCATTER*

Effect of Filtration on Intensity and Quality at 85 Kvp

Figure 5 shows the effects of filtration on intensity at the points denoted as A, B and C, in Figure 3. In addition, curve A' gives intensity values on the table top when the phantom resting on the instruments produces back scatter. It will be noted that after the addition of 3 mm of aluminum, intensities at A and A' decrease more and more slowly, but that intensities at B and C' continue to fall.

FIGURE 4 Effect of Field Size on Intensity (r per Minute) and on Quality ($\log D_a/D_s$) of Side Scatter 85-kvp, 4-ma, 1.67-mm Aluminum Filtration
 C = field margin 2.5 cm inside phantom edge
 C' = field margin 7.5 cm inside phantom edge (field and phantom centers coincide)

at a relatively constant rate. From this it seems that 3 mm of aluminum is about the optimal filtration in respect to intensity for fluoroscopic purposes.

Although these findings are somewhat at variance with those of Morgan,¹² they correspond closely enough to have significance. A filtration of 3 mm instead of 1.5 mm of aluminum does not noticeably diminish the luminescence of the fluoroscopic screen, yet it does decrease the exposure of the patient (35 per cent), and reduces to some extent (20 per cent) the intensity of the side scatter received by the examiner.

*The x-ray source was a Picker therapy machine with a 'Thermax tube.

is apparent that measurements made with one film emulsion cannot be referred to standards made with a different one. This drawback, however, can be minimized if one obtains a supply of the same film emulsion sufficient for a period of several weeks.

Because scattered x-radiation has a "harder" quality than the generating direct beam, standards for the measurement of scatter must be obtained by simultaneous exposure of film badges and minometers to an arbitrarily selected source. For moni-

ARRANGEMENT OF INSTRUMENTS

Figure 3 shows diagrammatically the general arrangement of tube, table and phantom, and the position of ionization chambers and badges in the experiments to be described. In all cases the phantom was composed of layers of "Masonite pressed wood," with over-all dimensions of 30 by 30 by 15 cm. Except in field-size studies the x-ray field was 15 by 15 cm, measured on the phantom top. The diagram shows the field centered so that the margin of the field is 2.5 cm inside the phantom edge. This field position was employed in the early studies, and is now the standard arrangement when film badges are calibrated for monitoring purposes. However, in the series of observations on filtration and on kilovoltage effects between 50 and 140 kvp, the field was centered on the center of the phantom.

At the point marked *A*, minometers were placed on the table surface with the phantom resting on top of them, in order to measure the intensity on the patient's skin when subject to direct beam and back scatter. (This is designated on the charts as *A'*). Because the back of the film badge was made of steel, and dental films carry a thin foil backing consisting of lead, antimony and tin, quality measurements at this site (to include back scatter) could not be made by means of films. Quality was determined, however, by both minometers (*h1*) and badges on the table top after removal of the phantom (*A*). Position *B*, directly on top of the phantom, represents the position of the palpating hand of the roentgenologist or the location of the fluoroscopic screen. Measurements were also made at *B'*, 12.5 cm above the phantom, but because these figures merely supplement the data obtained at *B*, they have not been presented. Lastly, both *C* and *C'* represent the position at the side of the table where the roentgenologist's lower torso comes nearest to the table edge, *C* indicates that the field margin is 2.5 cm from the phantom edge, and *C'*, that the field is centered on the phantom's center. Although these sites for the instruments were recognized as being somewhat arbitrary, it was believed that they were critical points where radiation should be measured.

For convenient reference, these arrangements of the instruments and apparatus are listed

- A* = table top without phantom (no back scatter)
- A'* = table top with phantom (back scatter)
- B* = phantom top
- B'* = 12.5 cm above phantom
- C* = side scatter, field 2.5 cm from the phantom edge
- C'* = side scatter, field 7.5 cm from the phantom edge (field and phantom centers coincide)

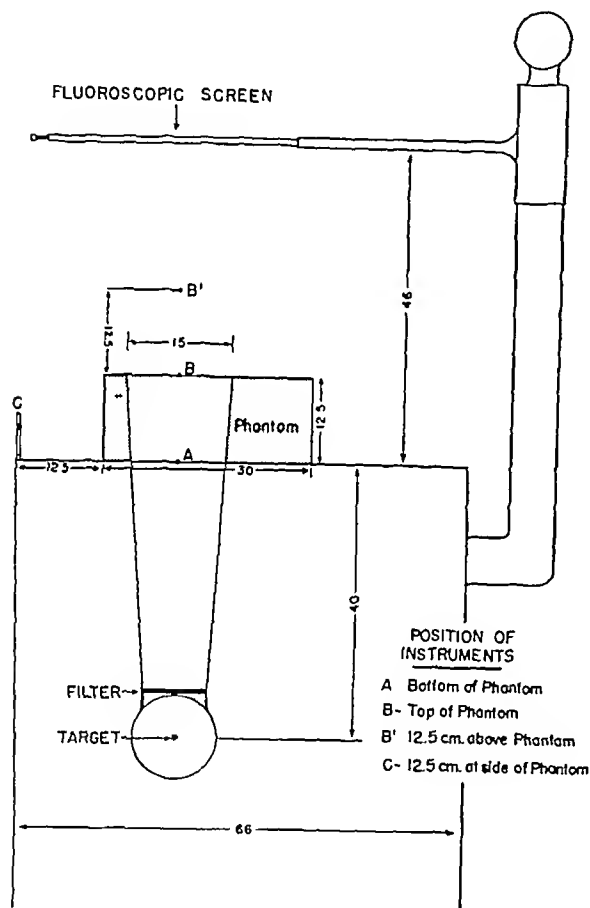

FIGURE 3 Arrangement of Apparatus and Instruments (Viewed from the Foot of the Fluoroscopic Table)

toring purposes, an easily reproducible and convenient source proved to be at a point 90° lateral to and 12.5 cm from a phantom placed on a fluoroscopic table, with the field margin 2.5 cm from the phantom edge, a filtration of 15 mm of aluminum, and a kvp of 85 (Fig 3 *C*). These filtration and kvp factors were chosen because of their general employment in fluoroscopic procedures. This site for the film badge was selected, because it approximates the position of the roentgenologist's lower torso when he is fluoroscoping a patient, and is the point of greatest intensity of scattered radiation.¹⁰

Effect of Voltage on Intensity and Quality with 1.5-mm Aluminum Filtration

Figure 8 shows the intensity at points *A*, *A'*, *B* and *C'*, for kvp values between 50 and 140. At *B* the intensity is about 10 times, and at *A*, it is 150 to 200 times that at *C'*. As presented in the figure, these data merely show that intensity increases with the kilovoltage, but when normalized to give a constant intensity falling on the fluoroscopic screen (Fig 8*A*), other useful information is obtained.

Intensity at *A'* now decreases rapidly and linearly from 50 to 105 kvp, but falls more and more slowly with further increase of kilovoltage. At *C'*, on the other hand, intensity rises slowly and almost linearly up to 105 kvp, and then increases at a continuously accelerated rate. In other words, raising the kilo-

corresponding kvp values are plotted (Fig 9), a linear relation obtains in the 85–140 kvp range, whereas $\log D_s/D_r$ values, similarly plotted, result in a series of hyperbolic curves (Fig 10). Between 50 and 85 kvp radiation quality measured both by hvl determinations and by the film method shows persistent irregularities. Moreover, the quality

FIGURE 6 Effect of Increasing Filtration with Aluminum on the Half-Value Layer (hvl) 85 kvp, 5 ma

A = table top (without back scatter)
B = phantom top
C' = side scatter (phantom and field centers coincide)

voltage above 105 increases (percentage-wise) the dosage rate of the examiner more than it decreases the dosage rate on the skin of the patient. From this it follows that optimal kilovoltage must lie within the 85–105 kvp range — provided the milliamperage is kept at 5 or below.

The effects of voltage on radiation quality are shown in Figure 9 and 10. When the hvl and the

FIGURE 7 Effect of Increasing Filtration with Aluminum on Quality as Measured by Film Badges 85 kvp, 5 ma

A = table top (without back scatter)
B = phantom top
C' = side scatter (phantom and field centers coincide) (Compare with Fig 6)

at 70 kvp in a large number of observations was consistently "harder" than should be expected. As this could not be due to errors of measurement it was presumed to be caused by additional energy of shorter wave lengths emitted at 69 kvp by the tungsten K-series. This phenomenon, however, requires further investigation.

Leddy, Cilley and Kirklin¹³ found that an 85 kvp direct beam, after passing through a 23 cm "Syncrest" wax phantom, had a half-value layer (hvl) of 4.5 mm of aluminum. In spite of differences in primary beam filtration, phantom thickness and phantom material, the half-value layer as measured by these investigators and by ourselves (*B* = 5.25 mm) is of the same order of magnitude.

It should be noted that side scatter at 85 kvp has a half-value layer of 5.9 mm of aluminum, while in the direct beam this value is not reached until

After all, the whole purpose of fluoroscopy is to enable the examiner to visualize contrasting shadows on the screen. Hence, if screen luminescence is satisfactory with 85 kvp, 5 ma and a filtration of 1.5 mm of aluminum, the same screen intensity can be maintained for all thicknesses of filter by varying the milliamperage. The resulting intensity

if hvl values for C' in Figure 6 are compared with corresponding $\log D_s/D_e$ values in Figure 7

From the data presented in these last two figures, increasing the filtration has a relatively slight effect on the *quality* of radiation measured at B and C' , but does have a considerably "hardening" influence on the radiation striking the table top (A). In Figure 6, in particular, hvl values at A obviously approach a maximum above which additional filtration causes practically no further increase. These measurements mean that the phantom so effectively filters out the longer components at B and C' that pre-filtration with extra aluminum does little except to diminish the intensity.

Because nearly maximal "hardness" at A (measured as the hvl) is reached with 3 mm of aluminum, this amount of filtration appears to be

FIGURE 5 Effect of Increasing Filtration with Aluminum on the Dosage Rate (Intensity in r per Minute) 85 kvp, 5 ma, 0 = Intrinsic Tube Filtration

A = table top (without back scatter)
A' = patient's skin-dosage rate (with back scatter)
B = phantom top intensity
C' = side-scatter intensity (phantom and field centers coincide)

values may be obtained by normalizing the data from curves A' and C' (Fig 5) for a constant screen dosage rate (B). These values are shown in Figure 5A. It will be seen that filtration up to 5 mm of aluminum does not affect the dosage rate received by the examiner, but it does attenuate the skin-dosage rate received by the patient—although more than 3 mm of aluminum produces relatively little further attenuation. Therefore this evidence, too, indicates that 3 mm of filtration is about optimal.

The effect of filtration on *quality* was measured both by half-value layer determinations (Fig 6), and by the film-density method, $\log D_s/D_e$ (Fig 7). In practically every instance, quality measurements from films were more consistent and reproducible than corresponding hvl determinations, especially when the intensity was low. This is quite evident

FIGURE 5A Data from Figure 5. Curves A' and C' Normalized to Maintain a Constant Dosage Rate (Intensity in r per Minute) at B (the Phantom Top or Fluoroscopic Screen) for All Values of Filter Thickness (Normal Screen Intensity Is Taken at the Value for 85 kvp, 5 ma with 1.5-mm Aluminum Filtration)

A' = patient's skin-dosage rate (with back scatter)
 C' = side-scatter intensity (phantom and field centers coincide)

optimal so far as *quality* is concerned. Therefore, taking all data into consideration, it seems fair to conclude that filtration by 3 mm of aluminum definitely increases protection of the patient, but that more than 3 mm adds little to the safety factor for either the patient or the roentgenologist.

important to point out the significance of certain of these observations in such a way that any person employing fluoroscopy can understand it

In the diagnostic range, between 50 and 140 k_vp, the quality of scattered radiation, formerly thought to be "soft," is now shown to be quite "hard." Consequently, the roentgenologist must protect himself and his associates from all of it so far as possible, and must regard all scattered radiation as sufficiently penetrating to reach the bone marrow

Present evidence (Fig 4) indicates that during fluoroscopy the patient can serve as a filter, and he should be used intelligently as such. It must be remembered that although the patient receives a large amount of radiation at any one examination, the roentgenologist over a long period of active practice — for example, thirty years — receives an enormously larger total dose. For this reason,

In addition, data derived from Figure 4 show that the spot film and fluoroscopic field size should be kept as small as possible, because, with a square field centered on the patient's mid-line, the examiner receives scattered radiation in amounts proportional to the square of the size of the field. Obviously

FIGURE 9 Effect of Increasing Kilovoltage on the Half-Value Layer (hvl) 5-ma, 1.5-mm Aluminum Filtration
A = table top (without back scatter)
B = phantom top
C' = side scatter (phantom and field centers coincide) Note the high hvl values at 70 kvp

the fluoroscopic beam should be centered on the patient as far distant as possible from the examiner and his aides. Although this might be regarded as a crude means of self-protection it at least reduces the intensity, even though it does not change significantly the quality of the side scatter

FIGURE 10 Effect of Increasing Kilovoltage on Quality, as Measured by Film Badges 5-ma, 1.5-mm Aluminum Filtration
A = table top (without back scatter)
B = phantom top
C' = side scatter (phantom and field centers coincide) Compare with Figure 9

careless technic in this respect can quickly result in a high degree of exposure

From the data shown in Figures 8 to 10, it is clear that one should not increase the kilovoltage to the range between 100 and 130 merely to increase the illumination of the screen. If the intensity on the screen is kept constant (Fig 8A), there may be certain advantages in increasing the kilovoltage. Nevertheless, it is imperative at all times to use as low a milliamperage as is compatible with proper visualization. However, the relation of kilovoltage and screen brightness requires further investigation with carefully controlled studies of the amount of radiation the patient receives, as well as the intensity and quality of the scatter

It may appear that the foregoing applies only to the roentgenologist and those assisting or observing with him, but analysis of the evidence reveals that nearly everything applicable to personnel ap-

well over 140 kvp. Furthermore, the rapid increase from 85 to 105 kvp of the side-scatter hvl (5.9 to 8.1 mm) must be taken into account when the optimal kilovoltage value is considered. From the foregoing, it appears that this value lies much nearer to 85 kvp than to 105 kvp. In any event, both side-scatter and direct-beam radiations filtered by the

employed. Empirical equations derived from the curves in Figures 9 and 10 are

$$A = \log D_s/D_i - 0.165 = \frac{0.53}{\text{hvl}}$$

$$B = \log D_s/D_i - 0.115 = \frac{0.995}{\text{hvl}}$$

$$C' = \log D_s/D_i - 0.168 = \frac{0.700}{\text{hvl}}$$

For monitoring purposes calibrations of film badges are made with 90° side scatter (C'). Since $\log D_s/D_i$ and $1/\text{hvl}$ are linear above 85 kvp, film badges must be exposed at two kilovoltages (85,

FIGURE 8 Effect of Increasing the Kilovoltage on the Dosage Rate (Intensity in r per Minute) 5-ma, 1.5-mm Aluminum Filtration

A' = patient's skin-dosage rate (with back scatter)
B = phantom top
C' = Side scatter (phantom and field centers coincide) Note the high intensity values at 70 kvp

patient have a "hard" quality and are capable of penetrating to the examiner's blood-forming organs

Summarizing and interpreting all data obtained thus far, it appears that the optimal factors for fluoroscopic procedures are a kvp of approximately 85, for this voltage and 5 ma, a tube filtration of 3 mm of aluminum

RELATION OF $\log D_s/D_i$ TO THE HALF-VALUE LAYER (HVL)

It can be shown from the data that $\log D_s/D_i$ is a reciprocal function of the corresponding half-value layer—that is, within the range 70 to 140 kvp for A and B, and within the range 85 to 140 kvp for C'. In all cases constants are involved, and these constants differ with each film emulsion em-

FIGURE 8A Same Data as those in Figure 8. Curves A' and C' Normalized to Maintain a Constant Dosage Rate (Intensity in r per Minute) at B (the Phantom Top or Fluoroscopic Screen), for All Values of Kilovoltage (Normal Screen Intensity Is Taken at the Value for 85 kvp, 5 ma with 1.5-mm Aluminum Filtration)

A' = patient's skin-dosage rate (with back scatter)
C' = side-scatter intensity (phantom and field centers coincide) Note the high intensity values at 70 kvp

and 105 or 120), in order to establish the constants noted above

SIGNIFICANCE OF THE PHYSICAL DATA

The material presented consists almost entirely of physical measurements. Admittedly such data are, at times, difficult for the roentgenologist, and often well-nigh impossible for the physician untrained in radiology, to interpret. It therefore seems

exposure to such a degree that occasional blood examinations can eventually be substituted for those now done twice a month

SUMMARY

A film badge that measures the quantity and quality of scattered radiation is described

Physical studies show that scattered radiation in the kilovoltage range between 50 and 140 has a "harder" quality than the direct beam that produces it.

The significance and the importance of these physical data to the roentgenologist are discussed

A radiation monitoring program is outlined, and some early results are commented upon

INFARCTION OF THE INTERVENTRICULAR SEPTUM*

DAVID LITTMANN, M.D.†

WEST ROXBURY, MASSACHUSETTS

THE electrocardiographic findings resulting from infarction of the interventricular septum were recently described by Roesler and Dressler‡ These investigators found that when the septum was involved so extensively as to include segments of both the anterior and posterior myocardial walls a characteristic electrocardiogram was regularly obtained This consisted of a posterior-myocardial-infarction pattern in the standard limb leads and an antero-septal picture in the leads from the precordium Interest in this condition led to a review of clinical and pathological material at the Veterans Administration Hospital in West Roxbury, Massachusetts

Over a period of twenty-seven months, from May, 1946, to August, 1948, there were 100 cases of acute cardiac accidents due to coronary-artery disease This group includes acute coronary thrombosis with and without myocardial infarction, myocardial infarction without demonstrable acute coronary occlusion and cases of atypical complaints and findings in which autopsy demonstrated recent myocardial infarction There were 25 deaths Autopsies were performed in 20 cases Of the anatomically examined group extensive infarction of the inter-

ventricular septum was observed in 11 Without exception there was considerable coincident involvement of the anterior or posterior walls of the left ventricle or both The papillary muscles were often infarcted

The pertinent data in this group of 11 patients with infarction of the interventricular septum are summarized in Table I

There were no women in this series because admissions at the West Roxbury Hospital are limited to men The ages varied from forty-seven to eighty, with a mean of sixty-one and three-tenths years History or physical findings of previous myocardial infarction, or both, were present in 6 patients, 2 of these also had angina pectoris Angina pectoris without a history of myocardial infarction was present in 4 cases One patient who had neither angina nor myocardial infarction had previously been studied for chronic pulmonary disease during which time there were no cardiac complaints or electrocardiographic abnormalities One patient had evidence of a gastric neoplasm and severe anemia In all but 1 patient there was clinical evidence of severe myocardial disease on admission There were signs of right-sided heart failure in 6, left-sided failure in 7, gallop rhythm in 3, embryocardia in 3 and extremely low blood pressure in 2 cases

Two of the patients had white-cell counts of over 20,000 (24,000 and 24,500) There were no other

plies to the patient as well. As shown in Figure 5, 5A, 6 and 7, an important safety factor so far as the patient is concerned is a filter of at least 3 mm of aluminum in addition to the inherent filtration of the tube. This markedly reduces the amount of radiation received by the patient and does not appreciably "harden" the quality of the side scatter.

It goes without saying that the radiologist should use adequate aprons and gloves. A fluoroscopic timer—preferably out of comfortable reach—should be utilized, and the time should be recorded for each examination. Fluoroscopy should be done rapidly. Diaphragms should be inserted in the cone of the tube to limit the field to the screen in all positions. To avoid exposing the top of the head and upper chest, the examiner's eye should be kept aligned with the center of the screen. Fluoroscopic rooms should be large in order to minimize back scatter from ceilings and walls. Properly protected equipment should be available, and it *must* be maintained in excellent condition at all times.

As a result of the observations presented here, it is quite apparent that the manufacturer has failed to provide adequate protection. The usual combination fluoroscopic-radiographic table and large (14" by 17") fluoroscopic screen is an obvious source of danger to the examiner. As provided in the ordinary spot-film device the screen increases the safety factor considerably, but only if the field is always kept well within the limits of the screen. The large screen should therefore be discontinued, and it will be, if the roentgenologist is fully aware of his exposure hazard. In addition to this, the table commonly employed today has an open Bucky slot, which transmits large amounts of scattered radiation. Some of the newer tables are enclosed in this dangerous area, but even certain of these are not enclosed on both sides *and* the bottom. An ideal combination table should be *fully* enclosed, including the portion of the Bucky slot not in actual use. If the manufacturer does not provide one in the near future, a safe, fully enclosed table with an under-table cone extending nearly to the table top should be designed for fluoroscopy only. Nevertheless, whatever future table design may be, it still behooves the radiologist to use any and all means possible that increase the protection of the patient, himself and his assistants.

MONITORING X-RAY PERSONNEL

In the Department of Radiology at the Massachusetts General Hospital, roentgenologists and other personnel subject to irradiation in diagnostic work wear film badges containing stock dental film (Du Pont No 550), while those handling radium or assigned to high-voltage therapy are given film badges carrying special sensitive film (Du Pont No 552). Male personnel wear the badge at belt level near the trouser watch pocket, and females on the anterior chest. At the end of each day the film badges

are removed from uniforms and kept together, so that all are subjected to the same temperature variations.

Every two weeks all badges are collected, the aluminum, steel and open windows are covered with lead, and the code numbers on the cadmium windows are recorded on the film beneath with 45 kvp x-ray. After the films are removed and fresh ones inserted, the film badges are promptly returned. All badges must contain films of the same emulsion lot number, otherwise, two or more sets of standards are required.

Before the films carried by personnel are developed, duplicate standards for both the stock and the special sensitive films are prepared—the latter by exposure of film badges to a calibrated radium source. When this has been done, the films worn by personnel, the film standards and unexposed blank films, are developed as has been previously described.

The film density under each window is then measured, net density and the log ratio of density beneath the aluminum and steel "windows" are calculated, and total *r* is obtained by location of the open "window" net-density value on a newly made linear graph. The resultant data are eventually recorded on the subject's record card along with the results of the blood examinations.

Examination of the blood consists in a hemoglobin determination (photoelectric-cell technic), a white-cell count and a differential count and description of the stained smear. These examinations are made every two weeks, and, so far as possible, examinations of female personnel are made *between* ovulation and menstruation. When blood samples are being obtained, each subject is questioned about recent health, with particular attention to minor infections or manifestations of allergy. Those persistently showing deviations from the normal are sent to the Staff Clinic for a complete physical examination.

While it is entirely too soon to attempt a correlation of blood changes and radiation exposure, certain observations on monitoring are of interest. In the first place, practically all the personnel in diagnostic work are now receiving less than 0.1 r over a two weeks' period, whereas personnel handling radium are showing a greater exposure, but so far less than 0.3 r in the same period. Secondly, the developed films clearly reveal individual carelessness when it occurs. The absence of film fogging on personnel in known hazardous positions is evidence of failure to wear the film badge, and sharp shadows of the metal "windows" characterize exposure to a direct beam.

Although the monitoring has only been in effect since September, 1948, most personnel have shown progressively lower exposures. Should this happy trend continue, it may well be that the psychologic effect of having to wear a film badge will reduce

exposure to such a degree that occasional blood examinations can eventually be substituted for those now done twice a month

INFARCTION OF THE INTERVENTRICULAR SEPTUM*

DAVID LITTMANN, M.D.†

WEST ROXBURY, MASSACHUSETTS

THE electrocardiographic findings resulting from infarction of the interventricular septum were recently described by Roesler and Dressler‡. These investigators found that when the septum was involved so extensively as to include segments of both the anterior and posterior myocardial walls a characteristic electrocardiogram was regularly obtained. This consisted of a posterior-myocardial-infarction pattern in the standard limb leads and an antero-septal picture in the leads from the precordium. Interest in this condition led to a review of clinical and pathological material at the Veterans Administration Hospital in West Roxbury, Massachusetts.

Over a period of twenty-seven months, from May, 1946, to August, 1948, there were 100 cases of acute cardiac accidents due to coronary-artery disease. This group includes acute coronary thrombosis with and without myocardial infarction, myocardial infarction without demonstrable acute coronary occlusion and cases of atypical complaints and findings in which autopsy demonstrated recent myocardial infarction. There were 25 deaths. Autopsies were performed in 20 cases. Of the anatomically examined group extensive infarction of the inter-

ventricular septum was observed in 11. Without exception there was considerable coincident involvement of the anterior or posterior walls of the left ventricle or both. The papillary muscles were often infarcted.

The pertinent data in this group of 11 patients with infarction of the interventricular septum are summarized in Table 1.

There were no women in this series because admissions at the West Roxbury Hospital are limited to men. The ages varied from forty-seven to eighty, with a mean of sixty-one and three-tenths years. History or physical findings of previous myocardial infarction or both, were present in 6 patients, 2 of these also had angina pectoris. Angina pectoris without a history of myocardial infarction was present in 4 cases. One patient who had neither angina nor myocardial infarction had previously been studied for chronic pulmonary disease during which time there were no cardiac complaints or electrocardiographic abnormalities. One patient had evidence of a gastric neoplasm and severe anemia. In all but 1 patient there was clinical evidence of severe myocardial disease on admission. There were signs of right-sided heart failure in 6, left-sided failure in 7, gallop rhythm in 3, embrocardia in 3 and extremely low blood pressure in 2 cases.

Two of the patients had white-cell counts of over 20,000 (24,000 and 24,500). There were no other

striking elevations of the white-cell count or erythrocyte sedimentation rates and no temperatures above 102°F

The clinical courses varied. With 2 exceptions the patients were desperately ill throughout much of their hospital courses. Two of these, however, had improved considerably and were expected to

levels during the period of bradycardia. When the block had cleared and the pulse increased the blood pressure promptly resumed its former levels.

All the 11 cases anatomically examined had coronary-artery sclerosis (Fig 1). In 2, however, there was no evidence of recent coronary occlusion. One with cancer of the stomach and severe anemia had

TABLE 1 *Data in 11 Cases of Infarction of the Interventricular Septum*

CASE No.	AGE	PERTINENT HISTORY	PHYSICAL FINDINGS	SIGNIFICANT LABORATORY FINDINGS	COURSE OF ILLNESS
1	57	Angina and hypertension for 1 yr. ankle edema for 5 days. pain 4 hr before entry	Cardiac enlargement, basal rales and ankle edema. blood pressure of 150/90	Abnormal urine. hemoglobin of 8.7 gm. sedimentation rate of 38 mm per hr. white-cell count of 10,300	Persistent angina with little or no effort. episodes of left failure. patient died suddenly and unexpectedly
2	53	Angina for 15 yr. dyspnea and edema for 3 yr. persistent pain for 12 hr	Cardiac enlargement, pitting edema	White-cell count of 19,600. sedimentation rate of 49 mm per hr	Pain returned on 6th day. angina on little or no effort. patient died suddenly and unexpectedly on 60th day
3	60	Hypertension and aortic stenosis for 7 yr. angina, dyspnea and edema for 2 yr. persistent pain for 2 days	Venous distention, enlarged heart, gallop rhythm, aortic murmur, rales and edema	White-cell count of 24,000. hemoglobin of 8 gm. blood sugar of 207 mg per 100 cc.	Persistent retrosternal pain. blood pressure of 90/80. return of pain 2 hr before death on the 6th day
4	57	Coronary thrombosis 7 yr. earlier. hypertension. persistent pain for 13 hr	Cardiac enlargement, slight cyanosis, embryocardia, gallop rhythm	White-cell count of 17,500. abnormal urine	Friction rub on 2nd day. bundle-branch block and then auriculoventricular dissociation with blood pressure of 90/70. temperature elevated to 102°F. patient died on 2nd hospital day
5	53	Heart attack 1 yr. before. angina for 6 wk. persistent pain for 12 hr	Cardiac enlargement, embryocardia, basal rales. blood pressure 74/48	White cell count of 24,000. sedimentation rate of 48 mm per hr	Temperature elevated to 102°F. severe chest pain recurred on 14th day. patient apparently recovering when he died suddenly on 18th hospital day
6		Gastric cancer. angina pectoris and ankle edema for 4 mo	Gallop rhythm, systolic basal murmur, blood pressure of 110/50. abdominal mass.	Hemoglobin of 4.3 gm. red cell count of 1,500,000	Persistent angina, decubitus, slight improvement with transfusion. gradual downhill course
7	47	Acute coronary incidents on 3 occasions. angina and dyspnea for 4 yr. recent total incapacity	Marked venous engorgement, cardiac enlargement, basal rales, pedal edema	Laboratory evidence of cirrhosis of liver	Repeated pulmonary embolism and infarction in spite of low prothrombin values. death after venous ligation
8	70	Hypertension, cardiovascular accident 2 yr. before, marked dyspnea for 4 days, crushing pain for 2 days	Venous distention, cardiac enlargement, pulmonary edema, cyanosis, friction rub	White cell count of 14,000. sedimentation rate of 36 mm per hr. abnormal urine	Transient auricular fibrillation, thrombophlebitis. patient died suddenly of cardiac rupture
9	80	Hypertensive heart disease, leg amputation for arteriosclerosis. pain for 12 hr	Cardiac enlargement, duplicated heart sounds, aortic systolic and diastolic murmurs	White cell count of 10,200. sedimentation rate of 34 mm per hr	Apparently good progress for 2 wk. one episode of transient collapse. patient died suddenly on 14th day while talking
10	56	Angina for 1 yr. congestive failure on 3 occasions. striking acute dyspnea for 24 hr	Cardiac enlargement, cyanosis and venous and hepatic engorgement, edema, blood pressure of 100/76	—	Thrombophlebitis and pulmonary infarctions. no response to therapy. gradual downhill course
11	60	Chronic pulmonary fibrosis, tearing precordial pain on and off for 4 days	Heart sounds distant, basal rales, blood pressure of 110/80	White cell count of 16,800. sedimentation rate of 36 mm. per hr. abnormal urine. nonprotein nitrogen of 55 mg per 100 cc.	Bundle-branch block followed by 3° auriculoventricular block with resultant drop in blood pressure to 50/40. patient apparently recovering when he died suddenly on 9th hospital day

recover. These and 2 who at no time appeared dangerously ill were among 5 patients who died suddenly and unexpectedly.

Auricular fibrillation was observed in 2 patients, appearing as a transient phenomenon in 1. Complete auriculoventricular block was seen in 2 cases. In 1 of these the blood pressure dropped to shock

only moderate sclerosis and narrowing, which was largely confined to the left anterior descending artery. Six showed fresh occlusions of the left anterior descending coronary artery, of these, 3 had associated involvement of the left circumflex branch, and 3 had older involvement of the right coronary artery. Three patients had fresh thrombosis of the

right coronary artery, and in each case older disease of the left anterior descending artery was present

The right ventricular side of the septum showed infarction in 3 of 11 cases studied and then only together with more extensive disease of the left side. In most cases from a third to a half (generally

The electrocardiographic pattern described by Roesler and Dressler was observed in 4 of the 11 patients, in 1 there was coincident right-bundle-branch block. In 2 the electrocardiogram was that of uncomplicated posterior myocardial infarction (Fig 2 and 3). Curiously, these were the only 2

	CASE No	EXTENT OF MYOCARDIAL INFARCTION	CORONARY VESSELS INVOLVED	ELECTROCARDIOGRAPHIC FINDINGS
	1	Lower third of left half of interventricular septum with contiguous segments of anterior and posterior walls to epicardial surfaces	Acute occlusion right coronary artery; older occlusion left anterior descending artery	Posterior infarction pattern in limb leads; antero-septal in pre-cordial leads; QRS complex 0.12 sec.
	2	Lower half of left half of interventricular septum with contiguous segments anterior and posterior left ventricular walls to epicardial surfaces	Acute occlusion right coronary artery; older occlusion left anterior descending artery	Posterior-infarction pattern in limb leads; antero-septal in pre-cordial leads; QRS complex 0.12 sec.
	3	Lower half of left half of interventricular septum with contiguous segments anterior and posterior left ventricular walls to epicardial surfaces	Extensive coronary sclerosis but no new or complete occlusion	Posterior infarction pattern in limb leads; antero-septal in pre-cordial leads; QRS complex 0.12 sec.
	4	Lower two thirds of left half of interventricular septum with large contiguous segments anterior and posterior left ventricular walls to epicardial surfaces; small isolated infarction left lateral wall	Acute occlusion left anterior descending artery; older occlusion right coronary and left circumflex arteries	Electrocardiographic pattern as above followed by right bundle-branch block and later 3° auriculo-ventricular block
	5	Lower posterior two thirds entire thickness of interventricular septum with large segment posterior left ventricular wall extending to but not including anterior myocardial wall	Acute occlusion right coronary artery; older occlusion left anterior descending artery	Pattern of posterior myocardial infarction; QRS complex 0.09 sec.
	6	Lower posterior three fourths entire thickness of interventricular septum with large contiguous segments of posterior left ventricular wall extending to but not including anterior myocardial wall	Minimal coronary sclerosis; no coronary occlusion	Pattern of posterior myocardial infarction; QRS complex 0.09 sec.
	7	Patchy infarction; lower half of left third of interventricular septum extending to anterior epicardial surface at apex; large area of sub-endocardial infarction lateral wall	Acute occlusion left anterior descending artery to left circumflex artery; old occlusion right coronary artery	Left bundle branch block
	8	Anterior lower half of left half of interventricular septum not including posterior left ventricular wall; entire contiguous anterior and lateral left ventricular wall with perforation laterally	Acute occlusion left anterior descending and left circumflex arteries	Left bundle branch block; auricular fibrillation
	9	Almost entire left half of interventricular septum and adjacent large segment of anterior wall of left ventricle; no posterior involvement	Acute occlusion left anterior descending artery; old occlusion right coronary artery	Left bundle-branch block
	10	Lower anterior half of left half of interventricular septum with local extension to right endocardial surface; large adjacent segment of anterior left ventricular wall	Acute occlusion left anterior descending artery; older occlusion left circumflex artery	Left bundle branch block; auricular fibrillation
	11	Lower anterior two thirds of left half of interventricular septum with large adjacent segment of anterior myocardial wall to epicardial surface; no posterior-wall disease	Acute occlusion left anterior descending artery; marked narrowing right coronary artery	Right bundle branch block; 3° auriculoventricular block

FIGURE 1 Electrocardiographic Findings, Vessels Involved and Extent of Myocardial Involvement in 11 Cases of Infarcted Interventricular Septum

a half) of the septal thickness was involved on the left ventricular side. It is of interest that patients who had the electrocardiographic picture of right-bundle-branch block demonstrated only left septal disease at autopsy. There were no septal perforations

deaths among 25 patients with the pattern of acute posterior infarction. Frank bundle-branch block was seen in 6 cases — 4 left and 2 right. Perhaps fortuitously, both patients with right-bundle-branch block also showed 3° auriculoventricular block, possibly as the result of bilateral bundle involve-

striking elevations of the white-cell count or erythrocyte sedimentation rates and no temperatures above 102°F

The clinical courses varied. With 2 exceptions the patients were desperately ill throughout much of their hospital courses. Two of these, however, had improved considerably and were expected to

levels during the period of bradycardia. When the block had cleared and the pulse increased the blood pressure promptly resumed its former levels.

All the 11 cases anatomically examined had coronary-artery sclerosis (Fig 1). In 2, however, there was no evidence of recent coronary occlusion. One with cancer of the stomach and severe anemia had

TABLE 1 Data in 11 Cases of Infarction of the Interventricular Septum

CASE No	AGE yr	PERTINENT HISTORY	PHYSICAL FINDINGS	SIGNIFICANT LABORATORY FINDINGS	COURSE OF ILLNESS
1	57	Angina and hypertension for 1 yr; ankle edema for 5 days; pain 4 hr before entry	Cardiac enlargement; basal rales and ankle edema; blood pressure of 150/90	Abnormal urine; hemoglobin of 8.7 gm; sedimentation rate of 38 mm per hr; white-cell count of 10,300	Persistent angina with little or no effort; episodes of left failure; patient died suddenly and unexpectedly
2	53	Angina for 15 yr; dyspnea and edema for 3 yr; persistent pain for 12 hr	Cardiac enlargement; pitting edema	White-cell count of 19,600; sedimentation rate of 49 mm per hr	Pain returned on 6th day; angina on little or no effort; patient died suddenly and unexpectedly on 60th day
3	60	Hypertension and aortic stenosis for 7 yr; angina, dyspnea and edema for 2 yr; persistent pain for 2 days	Venous distention; enlarged heart; gallop rhythm; aortic murmur; rales and edema	White-cell count of 24,000; hemoglobin of 8 gm; blood sugar of 207 mg per 100 cc	Persistent retrosternal pain; blood pressure of 90/80; return of pain 2 hr before death on the 6th day
4	57	Coronary thrombosis 7 yr earlier; hypertension; persistent pain for 13 hr	Cardiac enlargement; slight cyanosis; embryocardia; gallop rhythm	White-cell count of 17,500; abnormal urine	Friction rub on 2nd day; bundle-branch block and then auriculoventricular dissociation with blood pressure of 90/70; temperature elevated to 102°F; patient died on 2nd hospital day
5	53	Heart attack 1 yr before; angina for 6 wk; persistent pain for 12 hr	Cardiac enlargement; embryocardia; basal rales; blood pressure 74/48	White-cell count of 24,000; sedimentation rate of 48 mm per hr	Temperature elevated to 102°F; severe chest pain recurred on 14th day; patient apparently recovering when he died suddenly on 18th hospital day
6		Gastric cancer; angina pectoris and ankle edema for 4 mo	Gallop rhythm; systolic basal murmur; blood pressure of 110/50; abdominal mass	Hemoglobin of 4.3 gm; red cell count of 1,500,000	Persistent angina decubitus; slight improvement with transfusion; gradual downhill course
7	47	Acute coronary incidents on 3 occasions; angina and dyspnea for 4 yr; recent total incapacity	Marked venous engorgement; cardiac enlargement; basal rales; pedal edema	Laboratory evidence of cirrhosis of liver	Repeated pulmonary embolism and infarction in spite of low prothrombin values; death after venous ligation
8	70	Hypertension; cardiovascular accident 2 yr before; marked dyspnea for 4 days; crushing pain for 2 days	Venous distention; cardiac enlargement; pulmonary edema; cyanosis; friction rub	White cell count of 14,000; sedimentation rate of 36 mm per hr; abnormal urine	Transient auricular fibrillation; thrombophlebitis; patient died suddenly of cardiac rupture
9	80	Hypertensive heart disease; leg amputation for arteriosclerosis; pain for 12 hr	Cardiac enlargement; duplicated heart sounds; aortic systolic and diastolic murmurs	White-cell count of 10,200; sedimentation rate of 34 mm per hr	Apparently good progress for 2 wk; one episode of transient collapse; patient died suddenly on 14th day while talking
10	56	Angina for 1 yr; congestive failure on 3 occasions; striking acute dyspnea for 24 hr	Cardiac enlargement; cyanosis and venous and hepatic engorgement; edema; blood pressure of 100/76	—	Thrombophlebitis and pulmonary infarctions; no response to therapy; gradual downhill course
11	60	Chronic pulmonary fibrosis; tearing precordial pain on and off for 4 days	Heart sounds distant; basal rales; blood pressure of 110/80	White-cell count of 16,800; sedimentation rate of 36 mm per hr; abnormal urine; nonprotein nitrogen of 55 mg per 100 cc	Bundle-branch block followed by 3° auriculoventricular block with resultant drop in blood pressure to 50/40; patient apparently recovering when he died suddenly on 9th hospital day

recover. These and 2 who at no time appeared dangerously ill were among 5 patients who died suddenly and unexpectedly.

Auricular fibrillation was observed in 2 patients, appearing as a transient phenomenon in 1. Complete auriculoventricular block was seen in 2 cases. In 1 of these the blood pressure dropped to shock

only moderate sclerosis and narrowing, which was largely confined to the left anterior descending artery. Six showed fresh occlusions of the left anterior descending coronary artery, of these, 3 had associated involvement of the left circumflex branch, and 3 had older involvement of the right coronary artery. Three patients had fresh thrombosis of the

When both anterior and posterior myocardial walls with right-bundle-branch block Complete auriculoventricular block occurred in 2 patients who

FIGURE 3 Electrocardiograms in Case 6
The findings are those of uncomplicated posterior myocardial infarction

Roesler and Dressler electrocardiographic pattern had previously shown right-bundle-branch block was observed However, bundle-branch block was The pattern of simple posterior myocardial infarction

FIGURE 4 Electrocardiograms in Case 4
Note the simultaneous appearance of right-bundle-branch block and the Roesler and Dressler pattern in the second tracing This altered somewhat in the electrocardiogram obtained later the same day The last tracing was made on the day of death when 3° auriculoventricular block was present The interventricular block apparently changed from right to left-bundle-branch block This was interpreted as evidence that the idioventricular rhythm, which occurred during auriculo-ventricular dissociation, originated on the right side below the original area of block

encountered more frequently One of the patients showed the Roesler and Dressler pattern together tion was found in 2 patients who had extensive involvement of the septum

ment (Fig 4 and 5) In the 3 cases exhibiting the pattern of Roesler and Dressler without classic bundle-branch block, the QRS duration was 0.12 second Only the patients who during life showed the pattern of posterior infarction had QRS complexes of 0.10 second or less

DISCUSSION

From the data obtained in 11 fatal cases of myocardial infarction showing extensive involvement of the interventricular septum, it appears likely that the most frequent electrocardiographic phenomenon in addition to or aside from patterns of specific infarction is that of impaired interven-

trocardiographic evidence of infarction with bundle-branch block, the Roesler and Dressler pattern), the diagnosis might have been made in a total of 15 patients out of the original group of 100 There were 11 cases of myocardial infarction with bundle-branch block and 5 cases with the Roesler and Dressler pattern One patient had both Of those with bundle-branch block 3 recovered, and 7 of the 8 who died were examined post mortem Of these 6 had infarction of the interventricular septum, and 1 did not Of 5 patients exhibiting the pattern of Roesler and Dressler, 1 recovered Those who died all had involvement of the septum The patient who had bundle-branch block and the Roesler and Dressler pattern had septal infarction at autopsy

It is apparent from the patient who had myocardial infarction with bundle-branch block but no anatomic involvement of the septum that not all persons exhibiting this picture have infarction of the septum Similarly, as indicated by 2 patients who had septal infarction with electrocardiographic manifestations of uncomplicated posterior-wall involvement, infarction of the septum may occur without specific diagnostic evidence

It is therefore impossible to determine the exact incidence or mortality of extensive infarction of the interventricular septum It is likely, however, that the mortality is about 70 per cent or between two and three times that of the entire group

It is not clear whether the high mortality is the result merely of extensive myocardial destruction or whether it is a special manifestation of septal disease There is some evidence that the interference with conduction and the related tendency to arrhythmias noted in infarction of the septum materially diminished the chances of recovery The large incidence of septal infarction in this group of fatal cases is also difficult to assess It may be related to the demonstrated high mortality in septal diseases On the other hand, septal injury frequently occurs in patients with widespread or fatal coronary-artery disease

SUMMARY

Out of a group of 100 cases of acute coronary-artery disease 25 patients died, and 20 were examined post mortem Of these 11 demonstrated extensive infarction of the interventricular septum

The mortality of septal infarction could not be accurately determined but is considered to be approximately 70 per cent

FIGURE 2 Electrocardiograms Obtained in Case 1

There is evidence of posterior myocardial infarction in the limb leads and of anteroseptal infarction in the precordial leads (The Roesler and Dressler pattern)

tricular conduction or frank bundle-branch block Less commonly, the Roesler and Dressler pattern is noted, and still less frequently the picture of uncomplicated myocardial infarction In this series the pattern of simple infarction was always that of the posterior wall — no infarction of the anterior myocardial wall was seen Patients who anatomically had extensive involvement of the anterior wall together with septal disease invariably showed bundle-branch block Atriculoventricular dissociation, a condition rarely seen in myocardial infarction, was encountered twice in this group

If one can accept these findings as criteria of interventricular-septum infarction (clinical or elec-

FATAL JARISH-HERXHEIMER REACTION WITH SUDDEN ANEURYSMAL DILATATION AND COMPLETE BRONCHIAL OCCLUSION FOLLOWING PENICILLIN THERAPY*

WILLIAM C L DIEFENBACH, M D †

ALBANY, NEW YORK

IN 1895 Jarish¹ observed after treatment with mercury an accentuation of the syphilitic roseola, and in 1902 Herxheimer² described a reaction of the various syphilitic manifestations following the use of mercury. He suggested a hypersusceptibility of the treponemes to mercury and believed that the reaction was caused by endotoxins liberated upon death of the spirochetes.

The demonstration by Mahoney, Arnold and Harris³ and others that syphilitic lesions undergo rapid involution under penicillin therapy suggested the use of this drug in the treatment of cardiovascular syphilis. Various reports of therapeutic shock following the use of penicillin in late syphilis have appeared in the literature,⁴⁻⁶ and for this reason there has been considerable hesitancy on the part of cardiologists regarding its use. This uncertainty has not been shared by most syphilologists.⁷⁻¹⁰

In general, reactions to penicillin have been fewer and milder than those with any other form of treatment for syphilis to date. Nevertheless, as with any newly introduced drug, an increasing number and variety of side reactions are observed.¹¹⁻¹⁷ A fatal case following sudden aneurysmal dilatation with complete bronchial occlusion and massive collapse of the lung is presented.

CASE REPORT

J. J. (A.H. 85142), a 75-year-old, married Negro, was admitted to the Albany Hospital by ambulance on January 7, 1949, with a chief complaint of weakness and cough of 1 week's duration. The patient had enjoyed excellent health most of his life except for gonorrhea as a youth. He had worked as a tobacco auctioneer for a number of years and had subsequently worked as a janitor. There was no history of syphilis. The family history was noncontributory. The present illness had begun with curvza, followed by a cough productive of small amounts of mucoid sputum and some elevation of temperature. He was seen by a physician, who advised hospitalization.

The temperature was 102.2°F, the pulse 130, and the respirations 36. The blood pressure was 140/80 (right arm), 135/78 (left arm).

Physical examination showed a well developed but poorly nourished man who did not appear acutely ill, but was coughing frequently. External examination of the eyes was not remarkable, there was no Horner's syndrome. The pupils were equal and reacted to light and accommodation. He was edentulous, and hearing was diminished. There was increased anteroposterior diameter of the chest, with widened interspaces, and an area of dullness on the right over the fourth and fifth ribs. Bronchovesicular breath sounds and fine crackles were heard in this area. The left lung was clear. Except for tachycardia examination of the heart was within normal limits. The remainder of the physical and neurologic examination was noncontributory.

The urine was normal. Examination of the blood demonstrated a red-cell count of 4,800,000, with a hemoglobin of 13 gm., and a white-cell count of 19,400, with 85 per cent neutrophils. Blood for a Wassermann test was drawn. The fasting blood sugar was 84 mg and the nonprotein nitrogen 36 mg per 100 cc. Blood culture was negative, but subsequently *Streptococcus viridans* was isolated from the sputum. Roentgenograms of the chest showed an area of consolidation in the lower peripheral portion of the right upper lobe consistent with pneumonia. The aorta appeared to be enlarged to the left, and there were areas of calcification within it, which suggested the possibility of an aneurysm. The electrocardiogram showed left-axis deviation and evidence of myocardial damage.

The patient was given fluids intravenously on admission and 100,000 units of aqueous penicillin every 3 hours, on the following morning the temperature was normal. On the 3rd hospital day, he complained of dyspnea, and on physical examination the trachea was deviated to the left, with absent breath sounds anteriorly and posteriorly on the left side. Another roentgenogram showed some resolution of the previously described area of increased density in the middle right-lung field. Areas of increased density had developed throughout the entire left-lung field, with narrowing of the interspaces and shifting of the mediastinum to the left consistent with atelectasis. The report on the blood Wassermann reaction was + + + +. The clinical impression was that the patient had a syphilitic aneurysm and that a Jarish-Herxheimer reaction had occurred after the penicillin therapy of pneumonia, with sudden dilatation and complete occlusion of the left main bronchus and massive collapse of the left lung.

On the following day bronchoscopic examination disclosed, about 5 cm. above the carina, a large bulge in the posterior wall of the trachea, which was pulsating in a marked fashion. The bronchoscope could be introduced beyond this point and the carina was then identified, but the left bronchus was found to be completely occluded by an extrabronchial mass intruding upon the bronchial lumen. It was impossible to introduce the bronchoscope into the left bronchus, the right being completely normal. Subsequently a titer of 120 was obtained in the complement-fixation test for syphilis, and a spinal-fluid Wassermann test was + + + +.

The patient went progressively downhill, with a daily temperature elevation to 103°F, and died on the 58th hospital day with no essential change in the previously described physical findings.

Autopsy showed collapse of the left lung. The heart was not unusual, weighing 280 gm. There was a large saccular aneurysm of the arch and descending aorta, which measured about 10 cm. in diameter. The aneurysm, which was occluding the left main bronchus and compressing the lower 4 or 5 cm. of the trachea, was thin walled and contained a large rubbery clot that was loosely adherent. The bodies of the fourth and fifth dorsal vertebrae were eroded to a depth of 2.5 cm., and the intervertebral disks between them were normal.

DISCUSSION

The unpredictable Jarish-Herxheimer reaction, or so-called therapeutic shock, occurs after the first injection of an antisyphilitic drug. There is a local response at the injection site, a general response of fever and malaise and a focal exacerbation of symptoms. The focal response is the one of concern and principally so in tertiary syphilis, for its occurrence in over 50 per cent of patients with early syphilis treated with penicillin is not of conse-

*From the Department of Internal Medicine Albany Medical College and Albany Hospital.

quence^{11, 16} In late syphilis it may cause a fatal reaction as in the case described above In cardiovascular syphilis the edema and swelling of the syphilitic involvement about the coronary ostia may result in sudden closure of a coronary artery, or an aortic aneurysm may rupture In laryngeal syphilis a gumma may swell and cause asphyxia The reaction is thought to be the result of the sudden death of a large number of spirochetes, with the subsequent release of proteins and toxins from the treponemes It has also been observed to occur since the introduction of penicillin into antisymphilitic therapy

Moore,⁷ in 1947, using penicillin in 50 cases of cardiovascular syphilis with aortic aneurysm or aortic insufficiency, divided them into two groups One was initially treated with 1000 units gradually increased to average therapeutic dosage, and the other with 50,000 to 100,000 units from the start In neither group did any untoward reactions or damage occur as detectable by sedimentation rates, temperature, white-cell count and so forth Moore concluded that the Herxheimer reaction need not be greatly feared There is no proof, however, that antisymphilitic therapy heals cardiovascular lesions even though it heals visible and palpable visceral lesions Untoward reactions are observed, as in the case described above, in which penicillin was given for pneumonia before it was discovered that the patient had syphilis There were no clues in the history or physical examination until the serologic report returned several days later

SUMMARY

The Jarish-Herxheimer reaction in cardiovascular syphilis is described

An unusual fatal case, in which sudden aneurysmal dilatation, with complete bronchial occlusion and massive lung collapse, followed penicillin therapy for pneumonia, is reported

The suggestion is made that some caution be exercised in the penicillin treatment of elderly patients for conditions other than syphilis

ACUTE APPENDICITIS WITH CONCOMITANT SITUS INVERSUS

Report of a Case

WILLIAM GEORGE ABEL, III, M D * ' 1

NEW YORK CITY

SITUS inversus viscerum is uncommon, only 200 cases having been catalogued up to 1912 by Karashima¹. By 1925, approximately 160 more cases had appeared in the literature,² and in 1938 Larson³ estimated that over 475 cases had been reported. Adams and Churchill⁴ stated that situs inversus had occurred in 23 cases out of 237,112 admissions to the Massachusetts General Hospital. Sherk⁵ observed this condition in 10 cases among 347,000 hospital admissions. Willis⁶ reported 3 cases in 10,000 hospital admissions. LeWald⁷ recorded 29 cases in 40,000, and Francisco and Ongpin⁸ 36 cases in 126,000 x-ray studies. Guenther⁹ reported 3 cases in 22,000 autopsies, LeWald⁷ 1 case in 50,000 autopsies, and Francisco and Ongpin⁸ 4 cases in 10,000 autopsies. Over a forty-year period, approximately 10,000 cadavers were dissected at Columbia University College of Physicians and Surgeons, with but 1 case being discovered.²

Most writers on this subject believe that the transposed organs develop normally and that their anatomically abnormal site has no ill effect upon their usual function or upon the patient's well-being. Situs inversus appears to be twice as common in males as in females, and total transposition of the organs is far more common than partial inversion.¹⁰⁻¹⁴

HISTORICAL

Perhaps the earliest known record of situs inversus viscerum dates from the time of Aristotle, who noted transposition of organs in 2 animals.^{1, 12-14} Beck¹⁵ reports that the first recorded case in man occurred in the person of Marie de Medici, Queen of France. In 1824 the use of auscultation and percussion as diagnostic aids was first discussed by Küchenmeister.¹⁶ Vehsemeyer,¹² in 1897, was able to demonstrate this condition by means of the roentgen ray. Pol,¹³ in reviewing the literature in 1935, found 46 cases of left-sided appendicitis associated with situs inversus. Blegen,¹⁷ in 1949, records 144 cases of situs inversus, with 158 operations. He found that a diagnosis of situs inversus was made before operation in only 39 cases in which the patient was operated upon for appendicitis.

EMBRYOLOGY

Situs inversus viscerum should not be confused with failure of rotation or malrotation. In malrotation the viscera occupy their usual anatomic po-

sition, the abnormality occurring in the midgut. The midgut occupies the umbilical cord up to about the tenth week of intrauterine life when the coils of gut return to the abdomen, which has grown large enough to accommodate them. Under normal conditions the proximal jejunum leaves the cord first, passing from right to left in a counterclockwise direction, using the superior mesenteric artery as its axis. These coils are packed more and more to the left by the following loops of intestine until the cecum and ascending colon, which are the last to enter, lie in the right hypochondrium. If, however, the coils of gut return to the abdomen en masse, retaining the position occupied in the cord, the entire large intestine will be on the left side with the small intestine on the right and the terminal ileum entering the cecum from right to left. This condition is known as failure of rotation. When there has been partial rotation, the coils lying between nonrotation and their normal position, the anomaly is referred to as malrotation.^{1-4, 8, 9, 19} Many theories have been advanced in an attempt to explain the cause of situs inversus, but as yet no satisfactory, acceptable hypothesis has been advanced.

Karewski²⁰ divides the cases into congenital and acquired, and the causes into total transposition of the viscera, failure of descent of cecum, excessive length of normally located appendix and mobile cecum with adhesions binding it to the left side.

DIAGNOSIS

Situs inversus, per se, is usually diagnosed during routine physical examination and confirmed by appropriate x-ray studies or is discovered accidentally at operation. The diagnosis of appendicitis rests upon a fairly regular chain of clinical symptoms and physical signs that do not need to be discussed. The diagnosis of "left-sided" appendicitis should be suspected when there are a history of epigastric or periumbilical pain followed by nausea or vomiting, clinical finding of dextrocardia, tenderness in either lower quadrant and reversal of the stomach shown by barium swallow.

CASE REPORT

S S (B H 20503-48), a 14-year-old Italian boy, entered the hospital with the complaint of periumbilical pain. On the morning before his admission to the hospital he had experienced dull periumbilical pain which remained constant and did not radiate. He spent the day in bed and later that evening became nauseated and vomited several times. He had been anorexic since the onset of his illness. He had

*Assistant resident, Fourth Surgical Division, Bellevue Hospital.

had one normal bowel movement on the day of admission. He had not received any cathartic or enema. He had no urinary or respiratory symptoms. He entered the hospital approximately 28 hours after onset of symptoms.

The past history revealed that the patient had been attending the cardiac outpatient department for many years because of "reversed heart." This had not in any way limited his physical activities.

Physical examination revealed a well developed but undernourished boy who appeared acutely ill. He seemed to be more comfortable with his thighs flexed on his trunk. His skin was hot and dry, with no rash or petechiae. Positive findings were confined to the chest and abdomen. The point of maximum cardiac impulse was in the fifth interspace 8 cm. to right of the midsternal line. Regular sinus rhythm, with sounds of good quality, was heard. The abdomen was flat and muscular, with no rigidity or spasm. There were marked tenderness and direct rebound tenderness in the left lower quadrant, but none in the right lower quadrant. There was no abdominal scar or masses. Rectal examination revealed no tenderness on the right and marked tenderness on the left.

The temperature was 103.2°F by rectum, the pulse 100, and the respirations 20. The blood pressure was 110/70.

Urinalysis was negative. Examination of the blood disclosed a white-cell count of 13,750, with 82 per cent neutrophils. A chest plate revealed dextrocardia. A barium swallow showed a situs inversus of the stomach. A preoperative diagnosis of situs inversus viscerum with acute appendicitis was made, and after restoration of fluid and electrolyte balance the patient was taken to the operating room. The abdomen was entered through a left McBurney incision, and an acutely inflamed appendix was removed. Exploration revealed marked mesenteric adenitis, ileum entering the cecum from right to left, and a left-sided liver. The patient was up and about on the morning after operation and was discharged on the 7th day completely asymptomatic.

SUMMARY

Situs inversus is uncommon. A review of the literature with some statistics pertaining to the condition is given.

The embryology of nonrotation and malrotation is discussed.

Aids in the diagnosis of situs inversus complicated by appendicitis are briefly listed.

This condition should be considered in the differential diagnosis whenever a patient complains of left-sided pain.

A report of a case is given in detail.

MEDICAL PROGRESS

ACTIVE IMMUNIZATION (Concluded)

GEOFFREY EDSALL, M.D.*

BOSTON

TETANUS

Effectiveness of Toxoid

The results of tetanus-toxoid immunization in the United States Army in World War II have been presented in illuminating detail by Long and Sartwell,¹¹⁰ whose paper has been abstracted *in extenso* in the *Journal*.¹¹¹ Long⁸ has also presented a brief summary of this material. The remarkable results obtained in the United States Army have been so well publicized that it will suffice to present here only the essential facts. The procedure employed was to administer three doses of 1 cc each, at intervals of three to four weeks, followed by a single stimulating dose of 1 cc at the end of the first year, and an emergency booster dose upon the occurrence of a wound or other injury that might result in tetanus. During the early part of the war, booster doses were also given to personnel departing for a theater of operations, unless such a dose had been administered within the preceding six months, this practice was later eliminated. All told, 12 cases of tetanus occurred in the Army during World War II, in only 4 of which the patients had received a full primary immunizing course as well as a booster dose of toxoid. The tetanus rate per 100,000 wounded and injured was 0.44 if all cases are considered and 0.22 if cases with no active immunization are excluded. These rates may be compared with those of other periods in the United States Army: for World War I, 13.4 per 100,000, and from 1920 to 1941 inclusive, 2.4 per 100,000. By contrast, the reported incidence in the Japanese Army and Navy from 1940 through 1944 was about 10 cases per 100,000 wounded. Abundant additional evidence is cited by Long and Sartwell, to substantiate the extraordinary prophylactic effectiveness of tetanus toxoid properly administered.[†]

A recent review and study by Press¹¹² has analyzed the arguments for and against the routine use of tetanus toxoid. He cites old and new data that re-emphasize the danger of contracting tetanus from trivial or unrecognized injuries. He has collected 100 clinical cases of tetanus that, when added to numerous previous reports, make a total of 982 cases in which the degree of the infecting

injury was defined. Fifteen per cent of all these cases arose from "trivial injury." Three hundred and fifty-one of the entire group could be analyzed for the presence or absence of *any* known injury, 34.5 per cent were recorded as "injury unknown." These observations lend further support to the routine use of toxoid, since the residual immunity left by periodic inoculations of toxoid should afford tangible protection even against unrecognized infection.

Limitations of Effectiveness

The duration of this residual immunity and the degree and rapidity of response to a booster dose have yet to be sufficiently defined. McBryde and Poston¹¹³ measured the persistence of antitoxin in Negro children at various intervals after administration of two doses of alum-precipitated toxoid, given two and a half months apart. Their data may be analyzed according to a generally accepted (but probably conservative) standard of protection: the presence of at least 0.1 unit of antitoxin per cubic centimeter of serum. By this standard, the following numbers of children were still protected at the indicated interval after primary inoculation: after one year, 30 out of 33, after two and a half years, 13 out of 29, and after five years, 2 out of 15.

McBryde and Poston then measured the response to booster doses of varying size, and found that at one week after a stimulating dose given at either two and a half or five years subsequent to primary immunization, a tenfold to eight-hundred-fold rise in antitoxin titers was obtained. The degree of response varied according to the size of the stimulating dose employed, but not in a simple linear proportion. For example, in the group injected two and a half years after primary inoculation, 1 cc produced an average titer of 7 units, 0.1 cc produced 3 units, and 0.004 cc produced 0.3 unit. The results after a five-year interval were closely similar.

Comparable findings in a larger group of subjects have been reported by Wishart and Jackson.¹¹⁵ They observed a sevenfold geometric mean rise in titer four weeks after a subcutaneous booster dose of 0.1 cc, and a thirty-two-fold rise after 1.0 cc of toxoid. Since 1 out of 67 subjects failed to reach a "protective" titer after receiving 0.1 cc, whereas all of 55 subjects reached or exceeded such

evidence as was offered to show that the vaccine afforded protection was counterbalanced, in the minds of most phthisiologists and health officers by the belief that its use might prove not only useless but also hazardous. Perhaps the story would have been different had Calmette been able to afford the expense involved in adequate laboratory studies before the vaccine was employed in human beings. There is a wistful comment, in one of the papers of Calmette and Guérin²² reporting on the immunization of cattle—

It would be desirable if this method could be tried more extensively in a larger number of animals and followed during a period of years corresponding to the average life of cattle in order to define its practical value. Unfortunately, actual economic conditions oblige us to await more favorable circumstances for the purchase and the conservation of a sufficiently significant herd.

One wonders how many studies such as this have been left hanging in a state of indecision for many years because of inadequate facilities for their evaluation at the start.

Results of Controlled Studies

At all events there is now a large accumulation of controlled evidence regarding the ability of BCG to reduce the incidence of tuberculous infection. The first such studies appear to have been those of Heimbeck and his associates²³ who observed that the incidence of clinical tuberculosis in tuberculin-negative medical or nursing students was very much higher than that among those who were tuberculin-positive when first enrolled. These investigators subsequently found that the administration of BCG to the tuberculin-negative groups produced as much as a sevenfold reduction in the incidence of subsequent clinical tuberculosis as compared to the unvaccinated negative reactors. In Denmark a recent outbreak of tuberculosis in a girl's school arising from an infected teacher gave striking support to the efficacy of vaccination.²⁴ Among 105 tuberculin-positive pupils 2 cases of tuberculosis occurred during a three-year period, among 106 tuberculin-negative pupils who had been vaccinated with BCG there were 2 cases, whereas among 94 unvaccinated tuberculin-negative pupils there were 41 cases with 1 death.

On this continent, several studies have been initiated during the last twenty years with varying results. Levine, Vogel and Rosenberg²⁵ and Levine and Sackett²⁶ continued a study program begun earlier by Park et al.²⁴ The earlier series (1926-32) in which infants were vaccinated or not according to the choice of their parents had shown 0.68 per cent tuberculous deaths in 445 vaccinated infants as against 3.38 per cent in 545 controls. Strict alternation in selecting controls was applied in the second series (1933-44) the death rates then became 1.41 per cent in 566 vaccinated infants as against 1.51 per cent in 528 controls. Levine and Sackett

concluded that the favorable results of the first series had been weighted by the inevitable tendency to vaccinate children of the more intelligent and co-operative parents.

Aronson and Palmer²⁷ have reported a six-year study of BCG vaccination in 1550 tuberculin-negative North American Indians 1457 closely comparable subjects being observed as controls. Careful follow-up studies included x-ray examination, tuberculin tests, histories of exposure to tuberculosis (21.4 per cent in those vaccinated and 19.8 per cent in the controls) and determination of the cause of death when ascertainable. Among the vaccinated subjects 40 cases and 4 deaths from tuberculosis occurred, compared to 185 cases and 28 deaths in the controls. Thus vaccination appeared to exert a fourfold protection against the disease and a sevenfold protection against death from tuberculosis.

Rosenthal and his associates²⁸ have completed a ten-year study of 1417 normal newborn infants given BCG vaccine, compared with 1414 controls. Eleven and 39 cases of tuberculosis respectively, developed—more than a threefold protection rate. Among infants definitely exposed to tuberculosis, there was 1 case in 98 vaccinated subjects against 4 cases among 63 random controls subject to comparable exposure.

Ferguson²⁹ undertook to control with BCG the alarmingly high incidence of tuberculosis in student nurses in Saskatchewan. Because of the urgent situation and the encouraging reports of BCG vaccination from Scandinavia it was decided not to maintain an unvaccinated control group; therefore the incidence of tuberculosis in tuberculin-negative nurses vaccinated from 1939 to 1943 was compared to that in similar unvaccinated groups observed from 1934 to 1938. The incidence of tuberculosis was 4.27 times higher in the unvaccinated nurses in general hospitals and 5.03 times higher in sanatorium nurses compared to the corresponding vaccinated groups. More recently Ferguson and Simes³⁰ have reported the results of a twelve-year study in 506 vaccinated and 503 unvaccinated Indian infants. 73 per cent of all subjects in the study were in families including both vaccinated infants and controls. Six cases of tuberculosis and 2 deaths from tuberculosis occurred in the vaccinated group as against 29 cases and 9 deaths in the controls—a protection rate of 4.81 against disease and 4.51 against death.

In general the studies cited above have led to a growing belief well established in parts of continental Europe but recent in this country, that BCG can be a valuable agent in the control of tuberculosis.³¹ Meanwhile, the studies referred to have been thoroughly combed for flaws by various authorities in the field. It has been pointed out that, in Levine's series the infant patients were not separated from their tuberculous environment pending the development of post-vaccinal immunity;

titers after receiving 10 cc, the authors suggest that the smaller dose is inadequate as a routine booster. It should be noted here that McBryde and Poston found that 0.1 cc, given intradermally five years after initial immunization, produced a response at least as good as that obtained with 10 cc subcutaneously. This supports the frequent observation of other workers with various antigens^{11 145 146} that a stimulating dose is highly effective when administered by the intradermal route.

Long and Sartwell¹¹⁰ likewise demonstrated the long persistence both of antitoxin levels and of the capacity to respond rapidly and adequately to a booster dose. Of 8 subjects tested four or five years after primary injections, all possessed 0.01 unit per cubic centimeter or more, 2 had titers of 1.0 to 5.0 units. One week after injection of the stimulating dose, 7 were tested again, and all were above 0.5 unit, 4 having titers of 5 to 20 units.

Thus, it appears to be fairly well established that detectable—and as a rule significantly high—titers of antitoxin persist for at least four or five years after primary immunization, and that a striking increase in titer will appear within a week of a booster injection. But cases of tetanus sometimes reach a fatal outcome in less than a week, so that the question arises, How soon will the titer begin to rise after injection of an emergency booster dose? Gold³¹⁶ has reported titrations on the fourth to the seventh day inclusive after booster doses in from 8 to 20 subjects. The first hint of a response was seen (in 1 subject out of 8) on the fourth day. A recent observation on 5 subjects titrated from the fourth to the tenth day inclusive³¹⁷ confirms these findings, and suggests that the response is at or near its maximum by the tenth day. Miller and his associates³¹⁸ have followed the initial response to a booster dose in about 100 subjects, finding that the best sequence (basic immunization with adsorbed toxoid, booster with fluid) induces a rise in most subjects by the fourth day and in all by the fifth day. Thus, it appears that in the presence of a low antitoxin titer a booster dose given immediately after injury may not always induce a response with sufficient speed to combat a fulminating tetanus infection, such as can occur when contaminated material is driven directly into the central nervous system. One is led therefore to the conclusion that optimum protection against tetanus may best be achieved by application of the following principles: adequate primary immunization, administration of periodic maintenance doses of toxoid, perhaps at intervals of approximately 4 years, administration of a booster dose after such injuries as may result in tetanus, and consideration of the prophylactic administration of antitoxin if such an injury has occurred within the meninges. A good description of a well planned and well organized industrial program of anti-tetanus immunization³¹⁹ and an excellent summary

of the principles and applications of reimmunization with tetanus toxoid³²⁰ have recently appeared and will be helpful to any physician planning the use of toxoid in individual patients or in groups.

Reactions

Wishart and Jackson³¹⁵ report the occurrence of severe local reactions in 4.7 per cent of their subjects receiving 10 cc as a booster dose. Although this frequency is not serious, they believe that it deserves to be reduced if possible, and state that preliminary trials have shown that refinement of the antigen may largely circumvent this problem. Pillemer and his associates^{321 322} have succeeded in preparing tetanus toxoid in a highly purified and concentrated form. This preparation has been sufficiently freed of anaphylactogenic constituents of the culture medium so that it will not cause shock in guinea pigs sensitized to the medium, the crude toxoid causing severe or fatal anaphylaxis in similarly sensitized animals. The method of purification is based upon precipitation of the toxoid substance with methyl alcohol in the cold, as has also been done by Pillemer with diphtheria toxoid.^{87 88} The successful application of such methods may make possible the distribution of toxoids that contain only the essential immunizing substance and perhaps also a stabilizing nonantigenic diluent, which will eliminate the risk of reactions to extraneous substances. The achievement of this objective may be hastened as a result of the series of studies by Mueller and his associates,^{323 325} which are directed toward the production of tetanus toxin in a medium consisting only of known chemical substances. Even when this is accomplished, however, there will remain the problem—as yet unimportant but likely to increase in frequency as more and more booster doses of toxoid are given—of sensitization and consequent untoward reactions caused by the toxoid protein itself.

TUBERCULOSIS

Attempts to prepare a vaccine against tuberculosis began with Koch's experiments with old tuberculin. It early became apparent that no significant protection against tuberculous infection could be achieved with anything less than whole bacilli as the antigen. Although many useful and sometimes promising studies have been carried out using killed organisms in laboratory³²⁶ or field³²⁷ experiments, major interest has for some years been focused on the use of the *Bacillus Calmette-Guérin* (BCG)—a vaccine derived from living tubercle bacillus by attenuation of a virulent bovine strain through prolonged cultivation on a bile-containing medium.³²⁸ For practically a generation, BCG has been the center of controversies regarding its safety or its efficacy. Unfortunately, the early clinical trials in France were not supported by adequate comparisons with valid control groups, so that such

evidence as was offered to show that the vaccine afforded protection was counterbalanced, in the minds of most phthisiologists and health officers, by the belief that its use might prove not only useless but also hazardous. Perhaps the story would have been different had Calmette been able to afford the expense involved in adequate laboratory studies before the vaccine was employed in human beings. There is a wistful comment in one of the papers of Calmette and Guérin²⁹ reporting on the immunization of cattle

It would be desirable if this method could be tried more extensively in a larger number of animals and followed during a period of years corresponding to the average life of cattle, in order to define its practical value. Unfortunately, actual economic conditions oblige us to await more favorable circumstances for the purchase and the conservation of a sufficiently significant herd

More recently, Ferguson and Simes³⁸ have reported the results of a twelve-year study in 306 vaccinated and 303 unvaccinated Indian infants, 73 per cent of all subjects in the study were in families including both vaccinated infants and controls. Six cases of tuberculosis and 2 deaths from tuberculosis occurred in the vaccinated group as against 29 cases and 9 deaths in the controls—a protection rate of 4.81 against disease and 4.51 against death.

In general the studies cited above have led to a growing belief, well established in parts of continental Europe but recent in this country, that BCG can be a valuable agent in the control of tuberculosis.³⁹ Meanwhile, the studies referred to have been thoroughly combed for flaws, by various authorities in the field. It has been pointed out that, in Levine's series the infant patients were not separated from their tuberculous environment pending the development of post-vaccinal immunity;

that the diagnosis of the cause of death was not always reliable, and that the absence of morbidity data makes interpretation of the over-all results of the study unsatisfactory³⁴⁰ Furthermore, Wallgren³³¹ shows that the results, if corrected to exclude subjects who were exposed to tuberculous infection prior to vaccination, are as favorable as those of Rosenthal Tytler³⁴¹ prefers to draw no conclusions from Levine's study On the other hand, favorable reports such as that of Aronson and Palmer³³⁵ have also been subject to criticism Levine³⁴² and Wilson³⁴⁰ point out that in this study the cause of death was not always verified, the degree of exposure to tuberculosis in vaccinated subjects and controls was only "fairly well" balanced, and the intensity of exposure to contacts was not quantitatively evaluated The question is raised whether good results in American Indians "can legitimately be transferred to civilized peoples having a higher degree of genetic immunity and exposed, as a rule, to a lower risk of infection"³⁴⁰ However, this last comment comes from the same paper that concludes, from Levine and Sackett's data, that "under ordinary conditions in which the infants are brought up in a tuberculous environment (BCG) seems to confer little, if any, protection" — that is, an infant in New York City must be segregated from heavy exposure to tuberculosis until he has established immunity Either line of reasoning could be correct, but it is hard to accept both at once

Rosenthal's studies are said to have included insufficient data on the causes of nontuberculous deaths, no comparative figures on duration of observation of controls and vaccinated subjects, large numbers of "lost" cases, inadequate histories of tuberculous contacts and so forth^{340 342} Ferguson's study is admittedly weakened by the acknowledged lack of concurrent controls, and Heimbeck's classic studies have been questioned³⁴⁰ because of the complicated system by which his subjects were classified, having been transferred from one group to another according to their successive Pirquet-test readings or subsequent history of tuberculosis However, it can readily be shown that, in Heimbeck's³⁴³ earlier (1936) reports, in which such transfers were not made, a significant degree of protection through BCG vaccination was nevertheless apparent, and finally, Wallgren³³¹ cites a recent report by Heimbeck that so arranges the subjects as to eliminate this defect

Thus, there is perhaps as yet no unassailably balanced and controlled study through which the effectiveness of BCG vaccination has been unimpeachably demonstrated It is doubtful whether such a perfect study can ever be carried out, since it would have to be a series of studies — on infants, children and adults, of various races and with varying degrees of exposure to tuberculosis For there will always remain skeptics who can truthfully say that one cannot with complete assurance

translate results from one group to another Such studies, moreover, would have to be set up against controls who were strictly comparable in age, race, degree of exposure, duration of observation, general health and living conditions, completeness of follow-up examination and so forth

Present Programs and Policies

Nevertheless, the mass of controlled evidence supporting the efficacy of BCG vaccination, considered along with the much larger uncontrolled groups, which are too numerous to be cited here but have been well tabulated by Levine,³⁴² has led to very extensive use of the vaccine in the last few years In Norway, BCG vaccination is reported to have been made compulsory³⁴⁴ for tuberculin-negative persons in the following groups: all persons in a tuberculous environment, doctors, nurses, hospital workers and other groups with a high tuberculosis morbidity, men liable for military service, and children of school-leaving age, students and so forth A widespread voluntary immunization program is going forward in Sweden³⁴⁵ and Denmark³⁴⁶

In 1946 the United States Public Health Service undertook the sponsorship of extensive trials of BCG vaccination,^{346 347} laying out a carefully controlled program and using vaccine furnished by a single laboratory New York State has undertaken a somewhat similar program, under the direction of Birkhaug,³⁴⁸ who has for a number of years been concerned with this problem At much the same time a joint committee representing various tuberculosis-control agencies in Great Britain sponsored an appraisal of the policy to be followed in that country The comprehensive report for this committee prepared by Tytler³⁴⁹ concluded that BCG was harmless, that the weight of available evidence indicated that BCG offered definite protection against tuberculosis in groups subject to undue risk from this disease, that the best method of application of the vaccine was probably by puncture or scarification, and that the technical difficulties involved in studies of the use of BCG were such that a single, carefully controlled and supervised source of supply should be established The need for careful and continued evaluation of the vaccine through properly designed and controlled programs has been reflected in the conclusions of a second United States Public Health Service conference on the problem,³⁵⁰ in the stated policy of the American Trudeau Society³⁵¹ and in the promulgation of regulations for the use of BCG by the New York State Department of Health³⁵² The history and background of the developments in BCG vaccination that have underlain these decisions have been amply presented in recent reviews by Aronson³⁵³ and Birkhaug³⁵⁴

Complications

Thus, it may be anticipated that BCG vaccine will be employed in this country on an increasing scale. What, if any, are its dangers and limitations? First among the latter is the fact, observed in every study cited, that it does not provide 100 per cent protection. In this respect it differs from no other immunizing agent. Secondly, it does cause occasional untoward reactions. Holm³⁴⁵ observed an incidence of 0.7 per cent of abscesses or glandular suppuration among 3369 intracutaneous vaccinations. Difs³⁵⁵ has seen serious necrosis in 0.3 per cent of 6447 vaccinations, the incidence among school children running as high as 2 or 3 per cent. However, Wallgren reports that areas of reaction larger than 10 by 10 mm occur in only 2.8 per cent of subjects, he considers that the constant and growing spontaneous demand of parents in Sweden for BCG vaccination of their children is sufficient evidence that the reactions are unimportant.³⁴¹ Törnell³⁵⁶ finds that the incidence varies greatly with the physician performing the vaccination. Lomholt³⁵⁷ reports a case of lupus vulgaris developing at the site of vaccination. Various workers stress the likelihood of producing an abscess at the inoculation site if BCG is administered to a tuberculin-positive subject. On the other hand, Wallgren,³⁵⁸ from an extensive experience, states that there is no danger in vaccinating already infected persons, and Nègre and Bretey,³⁵⁹ in reviewing this field, find that focal and general reactions are induced in tuberculous patients only by injection of very large doses of BCG (1 mg) compared to the usual immunizing dose of 0.05 to 0.1 mg.

Technic of Vaccination and Vaccine Preparation

A decade ago Rosenthal³⁶⁰ developed the multiple-puncture technic for cutaneous BCG vaccination. This method has been employed since by others, including Birkhaug,³⁶¹ who has devised for the purpose a spring-action, multiple-point apparatus.³⁶² His experimental data³⁶¹ and certain of the available clinical data suggest that the cutaneous route induces a higher degree of immunity than intracutaneous inoculation, and it is the opinion of some that reactions are minimized with the use of the cutaneous route.^{349, 363} Its disadvantages, on the other hand, are said to be that it is in general somewhat slower in performance, the exact amount of inoculum cannot be determined, and the apparatus is difficult to sterilize³⁶⁴ and might theoretically cause some risk of transmitting serum hepatitis. These are technical difficulties however, which have already been largely obviated by appropriate technical advances. Finally, Malmros³⁶⁴ reports a relatively low tuberculin-conversion rate after cutaneous inoculation of BCG. Similar results obtained by Sigrid Holm are cited and criticized by Heimbeck,³⁶⁵ who calls attention to the low po-

tency of much of the tuberculin used in recent Scandinavian programs — a finding that is confirmed by Bøe.³⁶⁶ It is to be hoped that extensive parallel studies with the two routes for BCG inoculation will be carried out, so as to furnish a basis for their comparative evaluation, and that tuberculin of uniform potency will be available in all countries performing such studies, so that dependable comparisons can be made.

BCG cultures are not entirely stable, and difficulties with their maintenance have been reported.³⁶⁷ Furthermore, each batch of vaccine has a very short period of usefulness, usually set at eight to ten days. However, a Russian report³⁶⁸ offers some promise of providing a method for improving the stability of the filled product, and vacuum-dried preparations of high stability are now being prepared and tried in several laboratories.

Finally, it is of interest to watch developments in the experimental use of the vole acid-fast bacillus, a mycobacterium pathogenic only for murine animals. Several experimental studies³⁶⁹⁻³⁷¹ confirm the potency of the vole bacillus for animal immunization against tuberculosis, and one experimental study in man has been reported.³⁷² The subject has recently been reviewed by the investigator responsible for the original discovery.³⁷³

TYPHOID FEVER

Effectiveness of Vaccination

Holt⁷ has reviewed the major current trends in the control of typhoid fever by immunization, and brought up to date the classic chart of the incidence of typhoid and paratyphoid fevers in the United States Army since 1860. Except for a small outbreak in 1930, the annual rate in the Army has stayed consistently below 1 case per 10,000 strength since 1920, the peak rate in World War II being actually slightly below similar "peaks" in the pre-war years 1937 and 1940. Considering the insanitary conditions under which many troops were obliged to live in the field during combat, the absence of any significant rise in incidence of typhoid during this period is truly noteworthy. A "few hundred" cases occurred, all told, in the five years of World War II, however,⁷ some of which have been individually reported from a clinical standpoint³⁷⁴, others have also been studied in detail from epidemiologic and bacteriologic points of view.^{375, 376} The series reported by Tribby, Stock and Warner³⁷⁵ includes 45 United States Army personnel suffering from confirmed typhoid fever, and 10 with paratyphoid B fever. Such figures as these have led many observers to believe that typhoid immunization is of little value.

Cases among the immunized have likewise been reported from time to time in other groups. Margarik³⁷⁷ describes an epidemic in which 15.3 per cent of the vaccinated became ill, as against 28.5

that the diagnosis of the cause of death was not always reliable, and that the absence of morbidity data makes interpretation of the over-all results of the study unsatisfactory³⁴⁰ Furthermore, Wallgren³³¹ shows that the results, if corrected to exclude subjects who were exposed to tuberculous infection prior to vaccination, are as favorable as those of Rosenthal Tytler³⁴¹ prefers to draw no conclusions from Levine's study On the other hand, favorable reports such as that of Aronson and Palmer³³⁵ have also been subject to criticism Levine³⁴² and Wilson³⁴⁰ point out that in this study the cause of death was not always verified, the degree of exposure to tuberculosis in vaccinated subjects and controls was only "fairly well" balanced, and the intensity of exposure to contacts was not quantitatively evaluated The question is raised whether good results in American Indians "can legitimately be transferred to civilized peoples having a higher degree of genetic immunity and exposed, as a rule, to a lower risk of infection"³⁴⁰ However, this last comment comes from the same paper that concludes, from Levine and Sackett's data, that "under ordinary conditions in which the infants are brought up in a tuberculous environment (BCG) seems to confer little, if any, protection" — that is, an infant in New York City must be segregated from heavy exposure to tuberculosis until he has established immunity Either line of reasoning could be correct, but it is hard to accept both at once

Rosenthal's studies are said to have included insufficient data on the causes of nontuberculous deaths, no comparative figures on duration of observation of controls and vaccinated subjects, large numbers of "lost" cases, inadequate histories of tuberculous contacts and so forth^{340 342} Ferguson's study is admittedly weakened by the acknowledged lack of concurrent controls, and Heimbeck's classic studies have been questioned³⁴⁰ because of the complicated system by which his subjects were classified, having been transferred from one group to another according to their successive Pirquet-test readings or subsequent history of tuberculosis However, it can readily be shown that, in Heimbeck's³⁴³ earlier (1936) reports, in which such transfers were not made, a significant degree of protection through BCG vaccination was nevertheless apparent, and finally, Wallgren³³¹ cites a recent report by Heimbeck that so arranges the subjects as to eliminate this defect

Thus, there is perhaps as yet no unassailably balanced and controlled study through which the effectiveness of BCG vaccination has been unimpeachably demonstrated It is doubtful whether such a perfect study can ever be carried out, since it would have to be a series of studies — on infants, children and adults, of various races and with varying degrees of exposure to tuberculosis For there will always remain skeptics who can truthfully say that one cannot with complete assurance

translate results from one group to another Such studies, moreover, would have to be set up against controls who were strictly comparable in age, race, degree of exposure, duration of observation, general health and living conditions, completeness of follow-up examination and so forth

Present Programs and Policies

Nevertheless, the mass of controlled evidence supporting the efficacy of BCG vaccination, considered along with the much larger uncontrolled groups, which are too numerous to be cited here but have been well tabulated by Levine,³⁴² has led to very extensive use of the vaccine in the last few years In Norway, BCG vaccination is reported to have been made compulsory³⁴⁴ for tuberculin-negative persons in the following groups: all persons in a tuberculous environment, doctors, nurses, hospital workers and other groups with a high tuberculosis morbidity, men liable for military service, and children of school-leaving age, students and so forth A widespread voluntary immunization program is going forward in Sweden³⁴⁵ and Denmark³⁴⁵

In 1946 the United States Public Health Service undertook the sponsorship of extensive trials of BCG vaccination,^{346 347} laying out a carefully controlled program and using vaccine furnished by a single laboratory New York State has undertaken a somewhat similar program, under the direction of Birkhaug,³⁴⁸ who has for a number of years been concerned with this problem At much the same time a joint committee representing various tuberculosis-control agencies in Great Britain sponsored an appraisal of the policy to be followed in that country The comprehensive report for this committee prepared by Tytler³⁴⁹ concluded that BCG was harmless, that the weight of available evidence indicated that BCG offered definite protection against tuberculosis in groups subject to undue risk from this disease, that the best method of application of the vaccine was probably by puncture or scarification, and that the technical difficulties involved in studies of the use of BCG were such that a single, carefully controlled and supervised source of supply should be established The need for careful and continued evaluation of the vaccine through properly designed and controlled programs has been reflected in the conclusions of a second United States Public Health Service conference on the problem,³⁵⁰ in the stated policy of the American Trudeau Society³⁵¹ and in the promulgation of regulations for the use of BCG by the New York State Department of Health³⁵² The history and background of the developments in BCG vaccination that have underlain these decisions have been amply presented in recent reviews by Aronson³⁵³ and Birkhaug³⁵⁴

ferent method, would yield a product capable of protecting a mouse against 100 such challenge doses. These results are by no means unique, similar findings having been obtained elsewhere³³⁹. Thus, it is necessary to have definite knowledge of the potency of a vaccine, before its success or failure in a given situation can be properly assessed.

Advances continue to be made in the understanding of the antigenic components of the typhoid bacillus, and of the means by which they can best be utilized. Carlinfant³⁹⁰ has analyzed several rather technical aspects of the present knowledge of the much-explored but still inadequately understood "Vi" antigen, with particular reference to the selection of strains suitable for the production of vaccines of optimum antigenic composition. He offers evidence that vaccines killed by formalin or desiccation are superior in potency to those prepared by phenol and heat. Drysdale³⁹¹ has carried out a careful comparison of the standard phenol-killed vaccine and the alcohol vaccine developed by Felix.³⁹² No significant differences were found in mouse-protective potency between the two types of vaccine. Finally, Durand^{393, 394} has inactivated typhoid-paratyphoid A and B vaccine by the addition of di-ethyl or di-methyl-thiocarbamate, thereby apparently preserving the Vi antigen better than with heat killing or alcohol killing. These reports are but samples of the various studies on methods of improving the potency of typhoid vaccine, which are underway in many laboratories. It can be assumed with assurance that out of these studies there will come further improvements in the effectiveness of the vaccine.

Reactions

A contribution of the highest significance is the finding by Luippold, Longfellow and Toporek³⁹⁵ that injection of three doses of 0.5, 0.5 and 0.5 cc of vaccine gives as good an immunity as the standard schedule of 0.5, 1.0 and 1.0 cc — and that this modified schedule causes considerably fewer untoward reactions. Since up to this date no reaction-free typhoid vaccine or purified antigen has become available, it is important to take advantage of any valid means of reducing the incidence of undesirable reactions. Luippold, Longfellow and Toporek's modified-dosage schedule should be of considerable help in this respect, since it has been adopted by the Army, approved by the United States Public Health Service³⁹⁶ and recommended by the Massachusetts Department of Public Health.³⁹⁷

GENERAL CONSIDERATIONS

Aside from the problems related to the control of specific diseases, active immunization may be approached from several general points of view: combined immunization, choice of immunization route, reimmunization, antenatal and neonatal immunization, reactions to immunizations and so

forth. Each of these topics would justify a review in itself. Most of the knowledge developed in each of these fields, however, has been acquired in the study of a specific immunization problem, hence many such observations have been cited above under the appropriate heading or were mentioned in a preceding review.¹¹ In most instances there is not yet sufficient knowledge on which to base a generalization from such specific studies; in others, generalizations have been accepted only with reservations. An example of the latter is the observation, mentioned above,¹³²⁻¹³⁷ that repeated doses of influenza vaccine do not appear to induce successively higher antibody levels in the manner observed with most types of reimmunization. As another example, it has been found that, whereas the addition of pertussis vaccine to diphtheria toxoid enhances the effect of the latter, the reverse does not appear to be true.^{73, 398}

For these reasons, as well as in the interests of space conservation, data bearing on these topics have been cited only under the appropriate disease heading. However a few reports of particular interest and possible broad significance deserve mention.

Combined Immunization

Numerous studies cited above illustrate the antigenic effectiveness of this procedure. Its increased acceptance, coupled with the growing recognition of the importance of immunization in early infancy, has inevitably run headlong into the well established belief that diphtheria immunization in early infancy is relatively ineffective, owing to the persistence of maternally transmitted antibodies. This explanation has been strikingly confirmed by the studies of Cooke,⁹⁸ who administered combined diphtheria and tetanus toxoids to 284 infants from one to fourteen months of age. Tetanus antibodies developed equally well in all age groups, correlating with the complete absence of either passive or active tetanus immunity in the study group. The response to diphtheria toxoid was relatively poor in a significant percentage of the infants under six months old, however, and these subjects proved to be, for the most part, the very infants who were born with maternally inherited antibodies. Similar findings have been reported by di Sant' Agnese.¹⁸⁵

This evidence strengthens the case for separate administration of diphtheria toxoid after six months, pertussis vaccine preferably being given earlier (tetanus toxoid can be included at any convenient point). However, the findings of Bell⁷⁴ very clearly suggest that the adjuvant effect of combining a pertussis vaccine with diphtheria toxoid fully offsets — from a statistical standpoint — the opposing effect of passive immunity in early infancy. About 8 per cent Schick failures were observed by Bell in the very young infants receiving the

per cent of the unvaccinated, the cases in the former were said to have been mild, whereas in the unvaccinated they were generally severe. Jordan and Jones³⁷⁸ present a detailed description of 44 cases, among 80 observed during an outbreak in a contingent of vaccinated British troops, the course of the disease in this group was notable for its severity, but no information was available regarding the source, and hence the intensity, of the infection. Anderson et al.³⁷⁹ report 105 cases in inoculated British personnel in the Middle East, in whom the severity of the disease did not appear to have been altered by vaccination. Haedicke³⁸⁰ reports 4 rather mild and atypical cases among vaccinated laboratory workers. Typhoid infection in such personnel is not always mild, however, as was vividly brought home a few months ago by the death, from this disease, of a distinguished American specialist in enteric bacteriology, who had been repeatedly vaccinated. Rist³⁸¹ summarizes his observations in World War I, during which he saw 29 cases with 7 deaths among the vaccinated, and 27 cases with 5 deaths among the unvaccinated. No figures are given to indicate the relative numbers of vaccinated and unvaccinated persons from whom this sample is drawn, nor the conditions under which infection was contracted. Rendu,³⁸² whose iconoclastic analyses of immunization data of various kinds are noted in detail above under "Diphtheria,"^{66, 68} has compared the slow drop in typhoid incidence in Paris, where vaccination is said to have been used extensively, with the almost complete disappearance of the disease in New York City, where vaccination against typhoid is negligible but sanitary measures have been thoroughly applied. He cites numerous outbreaks of typhoid fever among vaccinated personnel, chiefly in the French Army but also in American troops^{374, 375} and states that "immunization of the American Expeditionary Forces has not prevented epidemics from occurring." He concludes that typhoid immunization is of little or no value. However, he is apparently unaware of recent reports in which the incidence of typhoid fever in vaccinated as against unvaccinated personnel could be compared.^{377, 383-385} all of which showed a significant lowering of the rate in immunized persons. Perhaps the most outstanding figures in this respect are those resurrected by Wilson and Miles³⁸⁶ from experiences during and before World War I. In British troops stationed abroad, up to 1913, 56 cases of typhoid fever had occurred among 10,378 vaccinated soldiers (0.54 per cent) as against 272 cases in 8936 uninoculated troops (3.05 per cent). In the French Army in 1915 the incidence was 0.095 per cent in the inoculated and 1.035 per cent in the uninoculated. More recently, Boyd³⁸⁷ has reported the experience of the British Middle Eastern Forces in 1940-42, in Allied and enemy prison camps. Several waves of typhoid fever occurred in Italian and German prisoners

held in British POW camps in this period. These outbreaks were later controlled in part by use of British vaccine, captured Italian vaccine having proved, on animal-protection tests, to be of inferior potency. On the other hand, some 25,000 British prisoners, in a highly insanitary camp near Benghazi, experienced no reported cases of typhoid fever, although they suffered about 12,000 cases of dysentery. The evidence strongly suggests that inoculation with a potent (British) vaccine gave a high level of protection, whereas the use of a less potent (Italian) vaccine, or no vaccine, led to high typhoid rates under insanitary conditions.

Preparation and Evaluation of Typhoid Vaccine

The somewhat conflicting results — and sharply conflicting opinions — cited above call for restatement of at least two elementary principles in the evaluation of any immunizing agent. The first is the fact that no such agent can ever be expected to give 100 per cent protection at all times. An agent of given efficacy may protect against an infecting dose of a given size or virulence for a variable but not limitless time, yet always there will be an infecting dose — or an interval since inoculation — that will overcome whatever protection was induced by the vaccination procedure employed. Hence the finding of cases of typhoid fever in vaccinated personnel means only that the vaccine does not always protect, this has been known for no less than thirty-five years. A satisfactory answer can only be obtained by comparison of genuinely comparable immunized and unimmunized groups — a situation that offers itself only rarely. The best controlled study of this type reported in recent years³⁸⁸ indicated that vaccination had given about 95 per cent protection against what was undoubtedly, to be sure, a rather small infecting dose. It is to be hoped that more controlled studies may be turned up as further opportunities arise.

The second factor in importance is apparent from the data cited by Boyd³⁸⁷ and from innumerable other studies — namely, that the potency of different batches of typhoid vaccine varies over a tremendous range. No world-wide agreement regarding the preferred method of potency testing has been reached, but the mouse-protection test — using either an actively immunized mouse, or a mouse inoculated with serum from an actively immunized person — is preferred in this country to the serum agglutinin titration. Bonnefoi et al.,³⁸⁹ at the Pasteur Institute, have recently confirmed the usefulness of the protection test. In the Division of Biologic Laboratories of the Massachusetts Department of Public Health it has repeatedly been demonstrated that a given batch of starting material could be made to yield a vaccine barely capable of protecting a mouse against the standard challenge dose of virulent typhoid organisms, whereas the same material, inactivated by a dif-

ferent method, would yield a product capable of protecting a mouse against 100 such challenge doses. These results are by no means unique, similar findings having been obtained elsewhere.³⁵⁹ Thus, it is necessary to have definite knowledge of the potency of a vaccine, before its success or failure in a given situation can be properly assessed.

Advances continue to be made in the understanding of the antigenic components of the typhoid bacillus, and of the means by which they can best be utilized. Carlinfant³⁹⁰ has analyzed several rather technical aspects of the present knowledge of the much-explored but still inadequately understood "Vi" antigen, with particular reference to the selection of strains suitable for the production of vaccines of optimum antigenic composition. He offers evidence that vaccines killed by formalin or desiccation are superior in potency to those prepared by phenol and heat. Drysdale³⁹¹ has carried out a careful comparison of the standard phenol-killed vaccine and the alcohol vaccine developed by Felix.³⁹² No significant differences were found in mouse-protective potency between the two types of vaccine. Finally, Durand^{393, 394} has inactivated typhoid-paratyphoid A and B vaccine by the addition of di-ethyl or di-methyl-thiocarbamate, thereby apparently preserving the Vi antigen better than with heat killing or alcohol killing. These reports are but samples of the various studies on methods of improving the potency of typhoid vaccine, which are underway in many laboratories. It can be assumed with assurance that out of these studies there will come further improvements in the effectiveness of the vaccine.

Reactions

A contribution of the highest significance is the finding by Luippold, Longfellow and Toporek³⁹⁵ that injection of three doses of 0.5, 0.5 and 0.5 cc of vaccine gives as good an immunity as the standard schedule of 0.5, 1.0 and 1.0 cc — and that this modified schedule causes considerably fewer untoward reactions. Since up to this date no reaction-free typhoid vaccine or purified antigen has become available, it is important to take advantage of any valid means of reducing the incidence of undesirable reactions. Luippold, Longfellow and Toporek's modified-dosage schedule should be of considerable help in this respect, since it has been adopted by the Army, approved by the United States Public Health Service³⁹⁶ and recommended by the Massachusetts Department of Public Health.³⁹⁷

GENERAL CONSIDERATIONS

Aside from the problems related to the control of specific diseases, active immunization may be approached from several general points of view: combined immunization, choice of immunization route, reimmunization, antenatal and neonatal immunization, reactions to immunizations and so

forth. Each of these topics would justify a review in itself. Most of the knowledge developed in each of these fields, however, has been acquired in the study of a specific immunization problem, hence many such observations have been cited above under the appropriate heading or were mentioned in a preceding review.¹¹ In most instances there is not yet sufficient knowledge on which to base a generalization from such specific studies, in others, generalizations have been accepted only with reservations. An example of the latter is the observation, mentioned above,¹³²⁻¹³⁷ that repeated doses of influenza vaccine do not appear to induce successively higher antibody levels in the manner observed with most types of reimmunization. As another example, it has been found that, whereas the addition of pertussis vaccine to diphtheria toxoid enhances the effect of the latter, the reverse does not appear to be true.^{73, 398}

For these reasons, as well as in the interests of space conservation, data bearing on these topics have been cited only under the appropriate disease heading. However, a few reports of particular interest and possible broad significance deserve mention.

Combined Immunization

Numerous studies cited above illustrate the antigenic effectiveness of this procedure. Its increased acceptance, coupled with the growing recognition of the importance of immunization in early infancy, has inevitably run headlong into the well established belief that diphtheria immunization in early infancy is relatively ineffective, owing to the persistence of maternally transmitted antibodies. This explanation has been strikingly confirmed by the studies of Cooke,⁹³ who administered combined diphtheria and tetanus toxoids to 284 infants from one to fourteen months of age. Tetanus antibodies developed equally well in all age groups, correlating with the complete absence of either passive or active tetanus immunity in the study group. The response to diphtheria toxoid was relatively poor in a significant percentage of the infants under six months old, however, and these subjects proved to be, for the most part, the very infants who were born with maternally inherited antibodies. Similar findings have been reported by di Sant' Agnese.¹⁸⁸

This evidence strengthens the case for separate administration of diphtheria toxoid after six months, pertussis vaccine preferably being given earlier (tetanus toxoid can be included at any convenient point). However, the findings of Bell⁷⁴ very clearly suggest that the adjuvant effect of combining a pertussis vaccine with diphtheria toxoid fully offsets — from a statistical standpoint — the opposing effect of passive immunity in early infancy. About 8 per cent Schick failures were observed by Bell in the very young infants receiving the

combined vaccine, as against 10 per cent failures in the older infants receiving the unmixed toxoid. There is now much additional evidence that combined antigens exert a potent effect in neonatal immunization, although the effect is in general less marked than that obtained in somewhat older infants. The various studies of di Sant' Agnese^{94, 187, 188} on neonatal immunization present ample evidence to this effect, adequate antibody levels against both pertussis and diphtheria were produced in most subjects in both age groups, but were definitely higher in the older group with respect to both diseases (the response to tetanus toxoid was excellent in both groups, no difference being disclosed by the method of assay). A booster dose six months after primary immunization produced equally high diphtheria antitoxin titers in both age groups, wiping out the pre-booster difference, but the booster response to pertussis vaccine was definitely better in the older group. Among older infants, there is more extensive evidence that combined antigens are effective, two recent reports by di Sant' Agnese³⁹⁹ and Fleming and his associates³⁹⁸ being among the most thorough studies in this field. Meanwhile, the Study Committee on Multiple Antigens of the American Public Health Association has been conducting extensive quantitative field evaluations of various antigen combinations, under its sponsorship have appeared a preliminary summary of recommendations⁴⁰⁰ and a report on reactions caused by various combinations⁴⁰¹, it is understood that the full report of this committee may shortly be available.

Reactions to combined antigens continue to be the chief stumbling block to their general acceptance, although reports in this respect vary between both extremes. Volk⁴⁰¹ has reported on the use of nine different preparations comprising six different combinations of diphtheria and tetanus toxoids, scarlet-fever toxin, pertussis vaccine and typhoid vaccine, including a preparation containing all five antigens. He found — not unexpectedly — that the most severe reactions were related to inclusion of scarlet-fever toxin, that reactions to typhoid vaccine and diphtheria toxoid were commoner in adults than children, that children had fewer local and more general reactions than adults, and that five-antigen preparations could be administered safely to special groups. These are comparative rather than absolute results, and hence are somewhat difficult to translate into actual practice. However, the subjective nature of a "reaction" was clearly observed by Volk, who found that the incidence of absenteeism from school was markedly reduced by advance explanation of the probable effect of the inoculations.

Oral Immunization

The subject of immunization, which can become somewhat dry when expanded beyond a few para-

graphs, has been resuscitated by Dolman⁴⁰² in an extensive and stimulating review of oral immunization. The conclusion reached — that there is "no present justification for even occasional resort to oral immunization" — is approached philosophically as well as scientifically by Dolman, with whose opening remarks this review may draw to a close.

Mankind seems to enjoy placing a wide variety of objects into the mouth, but displays a widespread dislike of the needle puncture. From these impulses, which are perhaps primordial, may derive much of the preference likely to be shown for oral ingestion rather than hypodermic injection of specific therapeutic and prophylactic substances, whether narcotics, endocrines, sulfonamides, antibiotics, or immunizing agents.

One might add that mankind possesses a correlated primordial instinct, to try anything once, and usually more than once. Immunization procedures (by any route) are no exception to this rule. It is true that much may be accomplished by the use of unusual procedures under certain specified conditions — for example, the sucking of toxoid pastilles for booster immunization.^{78, 79} However, if there is any one major theme running through the varied components of this review, it is that much is yet unknown in the field of active immunization, that decision is indeed difficult, and that experiment can without doubt at times be perilous. Much disappointment and disillusion may be avoided, if the discerning physician will insist that the experimental evidence be adequate, before introducing a new procedure into his practice. One needs only to recall the history of "cold vaccines," liquid pertussis antigen, "undenatured bacterial antigen" or the two-dose schedule for fluid diphtheria toxoid — not to mention the currently receding wave of high enthusiasm for influenza vaccine — to realize once again how much energy both the doctor and the patient can expend on bright but unfulfilled hopes in this field.

combined vaccine, as against 10 per cent failures in the older infants receiving the unmixed toxoid. There is now much additional evidence that combined antigens exert a potent effect in neonatal immunization, although the effect is in general less marked than that obtained in somewhat older infants. The various studies of di Sant' Agnese^{94, 187, 188} on neonatal immunization present ample evidence to this effect, adequate antibody levels against both pertussis and diphtheria were produced in most subjects in both age groups, but were definitely higher in the older group with respect to both diseases (the response to tetanus toxoid was excellent in both groups, no difference being disclosed by the method of assay). A booster dose six months after primary immunization produced equally high diphtheria antitoxin titers in both age groups, wiping out the pre-booster difference, but the booster response to pertussis vaccine was definitely better in the older group. Among older infants, there is more extensive evidence that combined antigens are effective, two recent reports by di Sant' Agnese³⁹⁹ and Fleming and his associates³⁹⁸ being among the most thorough studies in this field. Meanwhile, the Study Committee on Multiple Antigens of the American Public Health Association has been conducting extensive quantitative field evaluations of various antigen combinations, under its sponsorship have appeared a preliminary summary of recommendations⁴⁰⁰ and a report on reactions caused by various combinations⁴⁰¹, it is understood that the full report of this committee may shortly be available.

Reactions to combined antigens continue to be the chief stumbling block to their general acceptance, although reports in this respect vary between both extremes. Volk⁴⁰¹ has reported on the use of nine different preparations comprising six different combinations of diphtheria and tetanus toxoids, scarlet-fever toxin, pertussis vaccine and typhoid vaccine, including a preparation containing all five antigens. He found — not unexpectedly — that the most severe reactions were related to inclusion of scarlet-fever toxin, that reactions to typhoid vaccine and diphtheria toxoid were commoner in adults than children, that children had fewer local and more general reactions than adults, and that five-antigen preparations could be administered safely to special groups. These are comparative rather than absolute results, and hence are somewhat difficult to translate into actual practice. However, the subjective nature of a "reaction" was clearly observed by Volk who found that the incidence of absenteeism from school was markedly reduced by advance explanation of the probable effect of the inoculations.

Oral Immunization

The subject of immunization, which can become somewhat dry when expanded beyond a few para-

graphs, has been resuscitated by Dolman⁴⁰² in an extensive and stimulating review of oral immunization. The conclusion reached — that there is "no present justification for even occasional resort to oral immunization" — is approached philosophically as well as scientifically by Dolman, with whose opening remarks this review may draw to a close.

Mankind seems to enjoy placing a wide variety of objects into the mouth, but displays a widespread dislike of the needle puncture. From these impulses, which are perhaps primordial, may derive much of the preference likely to be shown for oral ingestion rather than hypodermic injection of specific therapeutic and prophylactic substances, whether narcotics, endocrines, sulfonamides, antibiotics, or immunizing agents.

One might add that mankind possesses a correlated primordial instinct, to try anything once, and usually more than once. Immunization procedures (by any route) are no exception to this rule. It is true that much may be accomplished by the use of unusual procedures under certain specified conditions — for example, the sucking of toxoid pastilles for booster immunization.^{78, 79} However, if there is any one major theme running through the varied components of this review, it is that much is yet unknown in the field of active immunization, that decision is indeed difficult, and that experiment can without doubt at times be perilous. Much disappointment and disillusion may be avoided, if the discerning physician will insist that the experimental evidence be adequate, before introducing a new procedure into his practice. One needs only to recall the history of "cold vaccines," liquid pertussis antigen, "undenatured bacterial antigen" or the two-dose schedule for fluid diphtheria toxoid — not to mention the currently receding wave of high enthusiasm for influenza vaccine — to realize once again how much energy both the doctor and the patient can expend on bright but unfulfilled hopes in this field.

The Secretary moved that the report of the Committee on Membership as presented to the Executive Committee be approved by the Council. The motion was seconded, and it was so voted.

Joint Report of the Committees on Public Relations and Medical Economics — Dr Harold R. Kurth, Essex North, *Secretary*, and Dr Elmer S. Bagnall, Essex North, *Chairman*.

Dr Bagnall presented the report as printed in the circular of advance information to councilors and moved the approval of the fourteen points (Appendix No 3). The motion was seconded.

The President recognized Dr James C. McCann (Worcester), who spoke at length (Appendix No 4) and moved the adoption of the amendment. Dr Elmer Bagnall seconded the motion.

Dr Charles C. Lund (Suffolk) questioned the wording of the amendment. Dr McCann then changed the wording of the amendment as follows:

Section 4. Voluntary prepayment group health plans, embodying group practice and providing comprehensive service, when practicable, sometimes offer their members adequate medical care. No such plan shall be obstructed in procuring enabling legislation. No physician participating in such a plan shall be denied, by reason of participation per se, 1, membership in established medical societies, 2, hospital-staff appointments dependent upon such society membership, 3, consultation courtesies by nonparticipating physicians on the usual plane of ethical relationship.

The President called for a vote on the amendment as corrected by Dr McCann. The motion was carried.

The President recognized Dr Basil E. Barton (Norfolk), who offered the following resolution from the Norfolk District Medical Society and moved its adoption: "Resolved, that the Councilors of Norfolk District Society desire the clarification of points 8, 10 and 13 of the principles enunciated in the Joint Report of the Committee on Public Relations and the Committee on Medical Economics, before they can vote on it."

The motion was seconded, and it was so voted.

Dr Bagnall then clarified the principles from the point of view of the committees. Dr Barton questioned whether article No 13 referred to subsidies to schools or students — if the latter, Norfolk would object. Dr Bagnall said that could not be answered specifically.

Dr H. B. Harris (Norfolk) moved that principle No 13 be stricken from the record. The motion was seconded.

Dr Vlado A. Getting (Middlesex South) said that if the motion carried, Massachusetts stood to lose \$3,000,000 for public health.

Dr Leroy E. Parkins (Suffolk) moved that principle No 13 be referred back to the committee for a report at the next meeting of the Council. The motion was seconded and so voted by a show of hands 84 to 68.

Dr Carl Bearse (Norfolk) made a motion that principle No 10 be stricken out since it prohibited free choice of physician. The motion was seconded. The Secretary pointed out that these principles had been drawn very carefully, and after long discussion by a group well versed in the problems involved.

Dr Lund spoke in favor of the principle as now amended. The President called for a voice vote, and the motion was defeated.

Dr Albert A. Hornor (Suffolk) made a motion that the word "encourage" be substituted for the word "support" in principle No 8. The motion was seconded, and it was so voted.

Dr Bernard Appel (Essex South) made a motion to insert the words "voluntary prepayment" before the word "plan" in principle No 10. The motion was seconded, and it was so voted.

The President then called for a vote on approval of the report as amended. The report was approved by voice vote.

Committee on Tax-Supported Medical Care — Dr Albert A. Hornor, Suffolk, *Chairman*.

Dr Hornor made a motion to approve the report (Appendix No 5). The motion was seconded.

Dr Bagnall expressed the wish that the committee would further discuss regular office fees for multiple first visits in home or office, and thereafter full fee for one patient and \$1.00 for each additional patient. Dr Hornor promised such discussion. The President put the question, and the motion was carried.

Committee on Legislation — Dr Curtis C. Tripp, Bristol South, *Co-chairman*.

Dr Tripp submitted the report as printed (Appendix No 6) and moved its approval. The motion was seconded and so voted.

Subcommittee on National Legislation — Dr Elmer S. Bagnall, Essex North, *Chairman*.

Dr Bagnall moved the adoption of the report as printed (Appendix No 7). The motion was seconded and so voted.

Committee on Publications — Dr Richard M. Smith, Suffolk, *Chairman*.

Dr Smith moved approval of the report as printed (Appendix No 8). The motion was seconded, and it was so voted.

Committee on Arrangements — Dr Harold G. Giddings, Middlesex South, *Chairman*.

Dr Giddings moved for approval of the report as presented (Appendix No 9). The motion was seconded, and it was so voted.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Annual Meeting, May 23, 1949

THE annual meeting of the Council was called to order by the President, Dr Daniel B Reardon, on Monday, May 23, 1949, at 7 00 p m, in the Ballroom of the Sheraton Hotel, Worcester

Two hundred and three councilors were present (Appendix No 1)

After opening the meeting, the President read the following obituary

JOHN HUGHES — Dr John Hughes, associate medical examiner and a practicing physician and surgeon in Pittsfield for twenty-five years, died suddenly on February 12 in Bristol, Rhode Island, where he was visiting his mother, who was seriously ill. He was sixty-six years old.

A native of Bristol, Rhode Island, Dr Hughes was born on January 21, 1883, son of Elizabeth Hamill Hughes and the late John J Hughes, and had lived in Pittsfield for more than a quarter of a century. He was a graduate of Providence High School, and had received his degree from University of Vermont College of Medicine in 1905. He took postgraduate work at the New York Postgraduate Hospital. He came to Pittsfield from Holyoke in 1924, where he had practiced for fifteen years. In 1937 he was appointed associate medical examiner by Governor Charles F Hurley.

He was a member of the Berkshire District Medical Society, and councilor from that district. He also belonged to the American Medical Association. Dr Hughes was a member of the staff of St Luke's Hospital and served as its president, and was also on the staff of the Pittsfield General Hospital.

At the request of the President, the Council stood in silent tribute to the departed member.

The President then announced the following interim appointments, which were approved by vote of the Council.

To the Committee to Meet with Massachusetts Nurses Association

Dr Richard B Cattell, *Chairman*
Dr Peirce H Leavitt
Dr David L Belding
Dr William F Wood
Dr Joseph A Holmes

Co-ordinating Committee

Dr Frank H Lahey, *Chairman*
Dr Charles J Kickham
Dr Leland S McKittrick
Dr Patrick J Sullivan
Dr John J Curley
Dr Walter G Phippen
Dr Frank W Snow
Dr Earle M Chapman
Dr Daniel B Reardon
Dr Arthur W Allen
Dr Donald Munro
Dr H Quimby Gallupe
Dr Eliot Hubbard, Jr
Dr Norman A Welch
Dr Elmer S Bagnall
Dr David L Belding
Dr Vlado A Gettung
Dr Augustus Thorndike
Dr Charles G Hayden

Dr Henry A Robinson
Dr Harold R Kurth
Dr Curtis C Tripp
Dr Joseph Garland
Dr John F Conlin

The Secretary presented the record of the meeting of the Council of February 2, 1949, as published in the *New England Journal of Medicine*, issue of April 7, 1949, and moved its acceptance. The motion was seconded, and it was so voted.

REPORTS OF COMMITTEES

Committee on Nominations — Dr Albert A Hornor, Suffolk, *Chairman*

The committee convened at 8 Fenway on April 13, 1949, and nominated the following officers of the Society for the year 1949-1950.

President, Dr Arthur W Allen
President-elect, Dr Leland S McKittrick
Vice-president, Dr Albert A Hornor
Secretary, Dr H Quimby Gallupe
Treasurer, Dr Eliot Hubbard, Jr
Assistant treasurer, Dr Norman A Welch
Orator, Dr John W O'Meara

Dr Hornor moved the acceptance of the report. The motion was seconded, and it was so voted. It was moved and seconded that the nominations be closed. It was so voted. It was moved that the Secretary cast one ballot for the list of nominees as presented. The motion was seconded, and it was so voted. The Secretary cast one ballot as directed.

Dr Reardon then presented Dr Arthur W Allen as the next president. Dr Allen replied that the vote of confidence was deeply appreciated and that no member of the Society receiving this great honor could possibly fail to be duly impressed. Dr Allen then gave an address, which was published in the June 16 issue of the *Journal*.

Dr Reardon then presented the other elected officers, and asked Dr Donald Munro to escort Dr Leland S McKittrick to the platform.

Executive Committee — Dr H Quimby Gallupe, Middlesex South, *Secretary*

The Secretary submitted the report of the committee (Appendix No 2), which met on April 20, 1949. He stated that 14 members of the committee were present at the meeting.

The Council by vote and without debate approved of the actions of the Executive Committee under its new business.

Dr Reardon put the question of the second amendment, and it was so voted. Dr Reardon put the question of the first amendment, and it was so voted.

Dr Ward then moved that Section 5 of the report be approved. The motion was seconded, and it was so voted.

Dr Ward then moved that the Council approve of the resolution concerning diabetes detection. The motion was seconded, and it was so voted.

Dr Ward then made a motion to approve the entire report as amended. The motion was seconded, and it was so voted unanimously.

Committee on Medical Defense — Dr Horatio Rogers, Suffolk, *Chairman*

Dr Rogers submitted the informational report as printed and moved its approval (Appendix No 15). The motion was seconded, and it was so voted.

Committee on Society Headquarters — Dr Frank R Ober, Suffolk, *Chairman*

Dr Ober presented the report (Appendix No 16) as printed. The Secretary then showed slides of the proposed location and buildings of the Boston Museum of Science on the banks of the Charles River at the dam. Dr Ober made a motion that the Council approve exploration of the possibilities implicated and report the findings at a future meeting of the Council. The motion was seconded, and it was so voted.

Committee on Industrial Health — Dr Daniel L Lynch, Norfolk, *Chairman*

Dr Lynch presented the report as printed (Appendix No 17) and moved its approval. The motion was seconded, and it was so voted. Dr Lynch made a motion that the Council approve the formation of a section on industrial health. The motion was seconded, and it was so voted.

Committee to Meet with the Massachusetts Hospital Association — Dr Albert E Parkhurst, Essex South, *Chairman*

Dr Parkhurst presented the informational report as printed (Appendix No 18) and moved its acceptance. The motion was seconded, and it was so voted.

Committee on Maternal Welfare — Dr Duncan Reid, Suffolk, *Chairman*

Dr Reid was not present. The President declared the report (Appendix No 19) informational. It was moved and seconded and voted to accept the report.

Committee on Post-Graduate Medical Education — Dr W Richard Ohler, Norfolk, *Chairman*

Dr Ohler presented his informational report as printed (Appendix No 20) and moved its acceptance. The motion was seconded, and it was so voted.

Committee on Medical Economics — Dr Elmer S Bagnall, Essex North, *Chairman*

Dr Bagnall presented the report as printed (Appendix No 21) and moved its acceptance. The motion was seconded, and it was so voted.

Committee to Make Recommendations as to Future Directors of the Blue Shield — Dr Leland S McKittrick, Suffolk, *Chairman*

Dr McKittrick presented his report as printed (Appendix No 22) and moved the appointments of the names submitted to become directors of Blue Shield, as indicated, until 1952 or 1951. The motion was seconded, and it was so voted.

Committee on School Health — Dr Ernest M Morris, Middlesex South, *Chairman*

Dr Morris presented the report as printed (Appendix No 23) and moved its acceptance. The motion was seconded, and it was so voted.

Subcommittee of the Executive Committee on Blue Cross-Blue Shield Problems — Dr Charles J E Kickham, Norfolk, *Chairman*

Dr Kickham presented his report as printed (Appendix No 24). He stated that for better public relations the whole aspect of fees should be investigated, as well as charges made to Blue Shield subscribers with incomes just over the fixed minimum.

He moved adoption of the recommendation as printed, "That a subcommittee of the Committee on Public Relations be constituted to investigate the problem and recommend an appropriate remedy." The motion was seconded.

Dr Arthur Allen said he approved and offered an amendment to the effect that the proposed committee explore the whole question of fees throughout the Commonwealth.

The motion was seconded, and it was so voted. The President then called for a vote on approval of the whole report as amended. It was so voted.

Committee on By-laws and Council Rules — Dr Edward P Bagg, Hampden, *Chairman*

Dr Bagg submitted the report (Appendix No 25) and added:

In addition to that, you received copies of the by-law changes that were approved at previous meetings of the Council. I should like to ask you to accept two corrections to the latter. In order to clarify the position of the new Committee on By-laws and Council Rules, I request that you allow the change from the word "under" to "to", there was omitted in the amendment, Chapter IV, Section 3, the word "on" in front of "by-laws". Therefore, it will read, "Resolved, that Chapter IV, Section 3 of the by-laws be, and hereby is, amended by the deletion of the word "and" (in line 9, page 14), after "Finance" and by the addition to the enumeration of standing committees the following words, "on by-laws and council rules."

The motion was seconded, and it was so voted. Dr Bagg then made the following motion:

Committee on Ethics and Discipline — Dr Ralph R Stratton, Middlesex East, *Chairman*

Dr Stratton moved adoption of all but the last paragraph of the report as printed (Appendix No 10) The motion was seconded, and it was so voted

Dr Stratton then moved to amend the report by striking out the last paragraph and substituting the following

About November 1, 1948, the committee received from the Eye and Ear Infirmary of the Massachusetts General Hospital a code of ethical conduct that was to govern them in their public relations They requested our examination of this code in relation to the code of ethics of the Massachusetts Medical Society

This code was studied and discussed at the meeting of the Committee on Ethics and Discipline on December 1, 1948 After this discussion, the committee unanimously voted that the code as proposed did not violate any of the provisions of the code of ethics of the Massachusetts Medical Society, nor of those of the principles of medical ethics of the American Medical Association

At the request of the Council, the matter was reconsidered at a meeting of the Committee on Ethics and Discipline on February 16 The Committee again reaffirmed that the code proposed by the Eye and Ear Infirmary did not violate the provisions of the code of ethics of the Massachusetts Medical Society, nor those of the principles of medical ethics of the American Medical Association

The motion was seconded.

Dr Donald Munro (Suffolk) stated that this amendment had cleared up objections to the report, but that there was a need for a code governing publicity that would be available to all hospitals, and he offered a second amendment as follows

That a committee of five be appointed by the President from representative districts of the Commonwealth to write a Massachusetts Medical Society Code to govern publicity They shall report at the next meeting of the Council

This motion was seconded, and it was so voted

The President then put the question of the first amendment, and it was so voted

Committee on Medical Education — Dr Chester S Keefer, Suffolk, *Chairman*

Dr James M Faulkner (Norfolk), for Dr Keefer, submitted the report as printed (Appendix No 11) and moved its adoption The motion was seconded, and it was so voted

Advisory Subcommittee on Medical Education — Dr Isaac R Jankelson, Norfolk, *Chairman*

Dr Jankelson submitted the majority and minority reports as printed (Appendix No 12) and moved their acceptance The motion was seconded, and it was so voted

Dr Jankelson then moved for the approval of the second recommendation in the majority report The motion was seconded, and it was so voted Dr Jankelson then moved the approval of the first recommendation of the majority report as the one

that had aroused the discussion and the disagreement by one committee member The motion was seconded, and it was so voted

Committee on Public Health — Dr Roy J Ward, Worcester, *Chairman*

Dr Ward presented the report as printed (Appendix No 13) Dr Ward then moved the approval of the first recommendation concerning the use of BCG vaccine by the Public Health Department of the City of Boston The motion was seconded, and it was so voted

Dr Ward moved approval of the second recommendation that greater emphasis be placed on education in the subject of nutrition in health The motion was seconded, and it was so voted

Dr Ward moved approval of the third recommendation concerning the pilot health clinics and further that a subcommittee of the Committee on Public Health representing the eighteenth districts to carry out the program be appointed and that the committee have power to act The motion was seconded

Dr Barton (Norfolk) moved the adoption of the following resolution "Resolved, that the councilors of the Norfolk District request from the Council an explanation of the mechanism of the origin and activation of pilot clinics proposed in the report of the Committee on Public Health before they can vote on it" The motion was seconded

Dr Ward then stated that it was the hope of his committee that a pilot clinic could do at one process what now is done in many for the detection of diabetes, heart disease, tuberculosis and so forth

Dr Appel said he thought the appointed committee should not be given power to act Dr W A R Chapin agreed with him

Dr Earle M Chapman (Suffolk) spoke at length for the recommendation Dr John J Curley (Worcester North) said the Executive Committee favored the pilot clinic plan Dr Lawrence Dame (Franklin) agreed with Dr Curley

The Secretary then read a document entitled "Health-Protection Clinics" (Appendix No 14), which had been presented to the Executive Committee Dr Maurice Fremont-Smith (Suffolk) spoke in favor of the plan Dr Donald Munro said he favored the plan as long overdue

Dr Leroy E Parkins moved an amendment that "pilot clinic" be substituted for "pilot clinics" The motion was seconded Dr Parkins moved a second amendment that a committee appointed be empowered to act in accordance with the eight principles in Dr Getting's program This motion was seconded

Dr Arthur Allen said he believed there should be more than one clinic Dr Parkins agreed to change his amendment to read "not more than five pilot clinics"

The Secretary read a letter from Dr Lawrence R Dame requesting a new section on ophthalmology and otolaryngology. On a motion duly made and seconded, it was voted to establish such a section.

The Secretary then stated that at a meeting of district society secretaries it was voted to request the Executive Committee to consider recommending annual registration of physicians in Massachusetts. The Secretary pointed out that once the Council had voted in favor and once had voted against annual registration. He said the General Court might write a bill for annual registration that might not be satisfactory to the Society.

The Secretary stated that no list of registered physicians is available for any purpose. Dr John Fallon, Worcester, said he was registered every year in Minnesota, that it was no burden to him, that it helped to keep out the unregistered illegal practitioners and that he favored it. The President stated that nurses and dentists register annually.

The Secretary pointed out that the legislation could include the publication of the list of registered physicians, and that such a list would be helpful to the Society. Dr John Curlev, Worcester North, moved that the Committee on Legislation and our legal counsel write a bill calling for annual registration. The motion was seconded.

Dr Dame, Franklin asked what would happen to a doctor who was late in registering. The Secretary stated that punishment, if any, would have to be written in the bill. Dr Dame pointed out that now physicians must be licensed in cities and towns and that not to be so licensed causes trouble for the doctor. Dr Welch said he had helped to defeat a similar bill and that the Board of Registration could not use the money obtained from fees for investigations. Dr Welch said that the defeated bill was poorly drawn. Dr Munro agreed with Dr Welch that the bill was bad and might have meant that a doctor would have to be re-examined if he failed to re-register.

Dr Gallupe stated that a doctor is registered only once and that re-registration is not accompanied by re-examination. He pointed out that no board has the full use of monies taken in, and that the board cannot investigate unregistered practitioners since that is the duty of the state police. Dr Charles J E Kickham said we shouldn't approve a bill until one is written. Dr Welch said bills are often changed markedly by the legislature. Dr Reardon stated the motion we approve of annual registration and recommend that a bill be written by the Committee on Legislation. The motion was seconded and defeated 11 to 3.

Dr Reardon then stated that the fourth matter for consideration under new business was referred to the committee by a meeting of officers and delegates of the Society to which the editor of the *Journal*, Blue Shield and Massachusetts National Physicians Committee members and critics of the American Medical Association leadership had been invited. It was the opinion of this group that the Executive Committee should consider recommending that our delegates to the American Medical Association be instructed to urge the House of Delegates to separate Dr Fishbein from any official position in the American Medical Association organization, take proper steps to end the National Physicians Committee hasten the plan for national enrollment of Blue Cross-Blue Shield as outlined by Dr Paul Hawley, reorganize the Council on Medical Service of the American Medical Association.

Dr Reardon stated that the second recommendation had been accomplished by the National Physicians Committee itself. Dr Munro asked if the item might be considered separately. Dr Reardon gave consent.

The Secretary stated that criticism concerning Dr Fishbein had been voiced at the joint meeting held on February 9 of the committees on Public Relations and Medical Economics, but that at a meeting of our co-ordinating committee the opinion was expressed that it would be better now to fight for things rather than to fight *against* other doctors. It is better public relations to let the public know we are not fighting amongst ourselves.

Dr Munro made a motion to disapprove of the first recommendation. The motion was seconded. Dr Munro thought it would be a tactical error to carry out the recommendation at this time. The President put the question to vote, and the motion was carried.

Dr Reardon then presented the third recommendation. Dr John Curlev said he believed Dr Elmer Hess would

APPENDIX NO 2

REPORT OF THE EXECUTIVE COMMITTEE

President Reardon called the meeting to order, and the Secretary called the roll. Councilors from Barnstable, Berkshire, Hampshire and Plymouth were absent. The Secretary stated that no business had been referred from the Council.

Under new business, the Secretary read a letter from Dr Walter E. Barton president of the Massachusetts Psychiatric Society, requesting the establishment of a section on psychiatry and neurology. It was moved and seconded that such a section be established. It was so voted without discussion.

In order to avoid as many errors as possible, I move that the proposed by-laws shall be submitted, for correction of any errors in form, to an assistant editor of the *New England Journal of Medicine*. I also move authorization and the publication of a new volume containing the Digest, By-laws, Code of Ethics and Medical Defense Act of the Society, and the Principles of Medical Ethics of the American Medical Association

The motion was seconded and so voted

Dr Bagg moved for approval of the report as a whole. The motion was seconded, and it was so voted

Committee on Diabetes—Dr Howard F Root, Suffolk, *Chairman*

Dr Root presented the report as printed (Appendix No 26) and moved its acceptance. The motion was seconded, and it was so voted

Committee on Veterans Affairs—Dr Harvey A Kelly, Suffolk, *Chairman*

Dr Kelly presented the report as printed (Appendix No 27) and moved its acceptance. The motion was seconded, and it was so voted

REPORT OF THE TREASURER

Dr Eliot Hubbard, Jr, Middlesex South, presented the report as printed (Appendix No 28) and moved its acceptance. The motion was seconded, and it was so voted

AUDITOR'S REPORT

Dr Gallupe read the report of the Auditing Committee (Appendix No 29), Dr Howard B Jackson, Norfolk, *Chairman*, and moved its acceptance. The motion was seconded, and it was so voted

The Secretary then moved that the report of the Executive Committee as amended be approved. The motion was seconded, and it was so voted

NEW BUSINESS

The President recognized Dr Barton, of Norfolk, who offered the following resolution presented by the Councilors of the Norfolk District Medical Society: "Resolved, that Norfolk District requests the Council for a delineation of the developments that have taken place regarding the report of the Committee on Special Services," and moved its acceptance. Dr Reardon said that under the Council Rules he would refer the resolution to the Committee to Meet with the Massachusetts Hospital Association

The President then recognized Dr William Elliot, Worcester, who presented the following resolution

That the committee from the Massachusetts Medical Society to confer with the Massachusetts Hospital Association be instructed to take steps to expedite the acceptance and practice of the principles enunciated by the Committee to Study Special Services, that the Secretary send a copy of the report of the Committee to Study Special Services to the Massachusetts Hospital Association

with the specific request that action be taken on the report by that body, and that the committee from the Massachusetts Medical Society to confer with the Massachusetts Hospital Association be requested to report to the Council at the October, 1949, meeting

Dr Reardon referred the resolution to the Committee to Meet with the Massachusetts Hospital Association

Dr Reardon then presented Dr Arthur W Allen, the president-elect, who read his committee appointments and the chairmen and secretaries of the new sections, and the delegates to the American Medical Association (Dr Allen's appointments were acted upon, and all approved at the annual meeting of the Society the next day)

The President said that if there were no further matters of new business, a motion to adjourn was in order. The motion was made, seconded and so voted at 11 00 p m

Dr Ward said the clinic would be carrying out the policies of the American Medical Association. Dr Getting said all that was asked for was approval in principle and not for the approval of a specific plan. Dr Lynch said the plan tied in with the report of the Committee on Diabetes and the Committee on Industrial Health, and he was strongly in favor of it. Dr Reardon put the question to a vote, and the motion was carried.

Dr Curley moved the endorsement in principle of the recommendation concerning local health unions and centers. The motion was seconded, and it was so voted. The Secretary then moved approval of the resolution beginning on line 31, through line 43, on page 13. The motion was seconded, and it was so voted.

The President then presented the report of the Committee on Medical Defense as informational, and it was accepted.

The President then presented the report of the Committee on Industrial Health with its resolution. The Secretary moved the acceptance of the report and approval of the resolution beginning on line 25, page 17. The motion was seconded, and it was so voted.

Dr Munro moved the approval of the resolution beginning on line 31, page 17. The motion was seconded, and it was so voted.

The President presented the report of the Committee to Meet with the Massachusetts Hospital Association as informational, and it was accepted.

The President presented the report of the Committee on Maternal Welfare, which was accepted as informational.

The President presented the report of the Committee on Postgraduate Education, and it was accepted as informational.

The President presented the report of the Committee on Medical Economics as informational, and it was accepted.

The President presented the report of the Committee to Make Recommendations as to Future Directors of Blue Shield. The Secretary moved that the nominations submitted be approved. The motion was seconded, and it was so voted.

The President presented the report of the Committee on School Health, and it was accepted as informational.

The President introduced Dr C J E Kickham, who presented the report of the Committee on Blue Cross-Blue Shield problems. Dr Kickham moved that the Executive Committee approve the recommendation beginning on line 19, page 23. This motion was seconded.

There ensued a long discussion concerning whether or not this matter was one of public relations or one for the Blue Shield local committees or the Committee on Blue Cross-Blue Shield problems. It was brought out in the discussion that complaints about excessive fees were not too many, but they were widespread and applied not only to Blue Shield cases but also to others, and that it was the opinion of most of the committee that the allegations should be investigated and a remedy suggested as a public-relations project. The President put the motion to a vote, and it was carried.

Dr Kickham then made a motion that the second recommendation, beginning on line 38, page 23, be approved in principle. The motion was seconded, and it was so voted without discussion.

Dr Reardon then presented the report of the Committee on By-laws and Council Rules. The Secretary moved the approval of the report. The motion was seconded, and it was so voted without discussion.

The President presented the report of the Committee on Diabetes. It was moved and seconded to approve the report with its resolution. It was so voted without discussion.

The President introduced Dr Harvey Kelly, who presented the report of the Committee on Veterans Affairs. He stated that it was the intention of his committee to have the material printed in the *Journal* for information to doctors. Dr John Curley and Dr Donald Munro objected because they believed this might be interpreted as interference by the Society in the practice of medicine by our doctors. Dr Munro moved that the report beginning on line 31, page 25, through line 47 be disapproved. The motion was seconded, and it was so voted.

Dr Munro moved that the first word "lastly" be deleted. The motion was seconded, and it was so voted without discussion.

Dr Munro then moved that the next recommendation of the report be approved after changing the fifth word in line 1 from "these" to "this". The motion was seconded, and it was so voted.

Dr Munro then moved that the last recommendation beginning on line 3, page 26, be disapproved. The motion was seconded, and it was so voted.

The President then introduced Dr Hubbard, who presented his report and moved its acceptance as informational. The motion was seconded, and it was so voted.

A motion to adjourn was made and seconded, and it was so voted at 5:15 p.m.

H. QUIMBY GALLUPE, *Secretary*

APPENDIX NO 3

JOINT REPORT OF THE COMMITTEE ON PUBLIC RELATIONS AND THE COMMITTEE ON MEDICAL ECONOMICS

The following principles were adopted on February 9, 1949 by the committees on Medical Economics and Public Relations of the Massachusetts Medical Society and a group of the staff of the Massachusetts General Hospital for presentation at the meeting of the Planning Committee of the American Medical Association on February 12, 1949.

1 We believe that the health of the people served by pre-payment insurance plans will be most benefited by medical care free of government administration and control.

2 We should like to call attention to the profligate waste and duplication in health programs operated by the Government in regard to both hospital beds and personnel as reported by the Hoover Commission. We believe that compulsory health insurance operated by the Government would result in similar inefficiency.

3 We believe that the manner of expression of policy on the part of the American Medical Association has served to diminish public confidence in that body to the serious concern of many of the members of the association.

We believe that the policy of the American Medical Association should be one of more active and enthusiastic support of constructive proposals for more equitable distribution of medical care.

Therefore, we suggest as constructive proposals worthy of support the following:

1 The objective of adequate medical care in our free society is to make available to everyone—regardless of race, color, creed, financial status or place of residence, every known essential preventive, diagnostic and curative medical service of high quality. The attainment of such medical care must necessarily be an evolutionary process which will require the co-operation of all concerned over a period of years.

2 The principle of voluntary prepayment health insurance should be the basic method of financing medical care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs and abolish the economic barrier to adequate medical services.

3 The success of any plan for medical care is dependent on the mutual co-operation of the public, those rendering professional services and the administrative agencies. This co-operation can be obtained only if those rendering the services are convinced that they will have a continuing authoritative voice in the formulation and execution of policies and plans, thereby assuming their proper share of responsibility.

4 Voluntary prepayment group health plans, embodying group practice and providing comprehensive service, when practicable, offer to their members excellent medical care. Hence such plans should be encouraged.

5 The people have the right to establish voluntary prepayment plans on any basis guarded by legal restrictions necessary to assure proper standards and qualifications.

6 Provision of adequate medical care for those unable to obtain it by voluntary prepayment plans or by direct payment is the responsibility of the local or state government. Part of the burden of this responsibility may be assumed by charitable agencies. Federal grant-in-aid

present a favorable report on National Blue Shield at the American Medical Association Delegates meeting Dr Reardon said National Blue Cross is already a fact Dr Kickham stated that the committee on Blue Cross-Blue Shield Problems had made recommendations to the Society in favor of a national Blue Shield enrollment service Dr Fallon said he believed it would be wise to favor a national Blue Shield scheme and moved that in place of this recommendation, the executive committee approve in principle the idea of a national Blue Shield enrollment agency The motion was seconded, and it was so voted

Concerning the fourth recommendation Drs Fallon and Curley suggested that our delegates might do well to sit in at meetings of the Council and talk with its members Dr Fallon thought it better not to interfere at this time Dr Munro moved to lay this recommendation on the table The motion was seconded, and it was so voted

The Secretary said he had a letter requesting the Society to take action concerning the parking of doctors' cars without interference by the police The only solution offered by the Secretary was to have the letters "MD" precede the license number on the doctors' cars Dr Curley moved that this matter be laid on the table The motion was seconded and so voted

The Secretary then presented a request from the chairman of the Committee on Physical Medicine that his committee be discharged and replaced by a single committee on physical medicine and rehabilitation The Secretary suggested that this matter be left to the discretion of Dr Arthur Allen, whose duty it is to appoint committees for the ensuing year Dr Curley moved the matter be laid on the table The motion was seconded and it was so voted

The Secretary then stated that Dr Reardon wished the committee to approve of his appointment of a co-ordinating committee to carry out the educational campaign of the American Medical Association as follows Dr Frank Lahey, chairman, Drs Charles J Kickham, Leland S McKittrick, Patrick J Sullivan, John J Curley, Walter G Phippen, Frank W Snow, Earle M Chapman, Daniel B Reardon, Arthur W Allen, Donald Munro, H Quimby Gallupe, Elmer Hubbard, Jr, Norman A Welch, John F Conlin, Elmer S Bagnall, David L Belding, Vlado A Getting, Augustus Thorndike, Charles G Hayden, Henry A Robinson, Harold R Kurth, Curtis C Tripp, Joseph Garland

Dr MacLachlan moved the approval of this committee The motion was seconded, and it was so voted The Secretary said this committee wanted the Council to approve the educational campaign of the American Medical Association Dr Curley made the motion to approve, which was seconded, and it was so voted

The Secretary presented the report of the Committee on Membership and moved its acceptance The motion was seconded, and it was so voted

Dr Reardon then presented the joint report of the Committee on Public Relations and the Committee on Medical Economics Dr MacLachlan said Middlesex East District approved all except principle 13 Dr Fallon said he believed principle 13 had been approved by the American Medical Association essentially as it stands Dr Reardon said he believed the fourteen points answered our critics who say we have done nothing constructive Dr Fallon said he believed all these points could be found in the records of the Council on Medical Service Dr Munro moved approval of the report as printed The motion was seconded, and it was so voted

Dr Reardon then asked the committee to consider the report of the Committee on Society Headquarters, which asks for authority to explore the possibility of obtaining headquarters for the Society, the Library and the Journal and to report its findings at a future meeting of the Council The President stated that the committee had met with officers of the Boston Museum of Science to discuss the possibility of joining with them at their proposed site on the Charles River at the dam The President then introduced Mr Bradford Washburn, the director of the museum, who described the project and showed slides of the location and the proposed buildings He pointed out the advantages of the location, the available parking space and easy transportation facilities Dr Kickham moved that the committee be given authority asked for and to report back to the Council The motion was seconded, and it was so voted

The President presented the report of the Committee on Tax-Supported Medical Care Dr Hornor said the original fees had been increased and moved the approval of his committee recommendation The motion was seconded, and it was so voted

The President presented the report of the Committee on Legislation, and it was accepted as informational

The President presented the report of the Committee on National Legislation, which was accepted as informational

The President presented the report of the Committee on Publications and it was accepted as informational (The publication of the *Directory* had already been approved in the budget for 1949)

The President presented the report of the *New England Journal of Medicine*, which was accepted as informational

The President submitted the report of the Committee on Arrangements It was accepted as informational

The President presented the report of the Committee on Ethics and Discipline and pointed out that the committee had reaffirmed its approval of the code of the Eye and Ear Infirmary Dr Curley moved acceptance of the report Dr Dame asked if the Council would be asked to approve every such code, and the Secretary thought this code was set up as a standard, which would be acceptable to the Society Dr Curley's motion was seconded Drs Dame, Munro and Welch expressed disapproval of the code on the grounds that it would allow an institution to circumvent the code of ethics of the Society Dr Munro moved that the motion be amended to the effect that the report be accepted, but that lines 5 to 14 of page 8 be disapproved This motion was seconded, and it was so voted

The President presented the report of the Committee on Medical Education, which was accepted, and its nominations for recipients of the awards were approved

The President introduced Dr Jankelson, who presented the report of the Advisory Subcommittee on Medical Education and stated that the area of agreement on the committee was large and the area of disagreement was narrow (Dr Gardner was not present to present his views) All except Dr Gardner believed that the proper certification body was the Board of Neurology and Psychiatry, and all were agreed that licensure by the Commonwealth to practice clinical psychology should not be supported at this time The Secretary moved approval of the majority report of the committee The motion was seconded, and it was so voted It was then moved and seconded that the lines 11 to 22, page 12, of the minority report be disapproved It was so voted

The President introduced Dr Roy Ward, who presented the report of the Committee on Public Health Dr MacLachlan moved that the committee's endorsement in principle of the limited investigation of the use of BCG vaccine be approved The motion was seconded, and it was so voted

Dr Munro then moved to approve in principle the recommendation that more emphasis be placed on education in the subject of nutrition on the undergraduate and graduate levels This motion was seconded, and it was so voted

Dr Munro moved to approve the committee recommendation concerning pilot clinics beginning on line 14, page 13 The motion was seconded

Dr Getting then pointed out that the project would be a joint effort of the Society, the hospital association, the community hospital, the Cancer Society, the Heart Association and others, including the Department of Public Health The clinics could evaluate the health screen, which is now restricted to separate groups The clinic would help combat socialized medicine. It would co-ordinate the efforts of voluntary groups The clinic would do no diagnostic work, but the report would go to the family doctor for diagnosis and treatment X-ray study would probably be limited to chest films The clinic would be in a community hospital, and the doctors would be paid The clinic would be publicized as a joint effort in the local newspapers The size of the city would be determined by the groups or committee conducting the study The project is the result of study including Dr Magnuson's report on a national level There would be no charge at the clinic, but opportunity would be given for contributions Dr Getting said patients would be referred to the clinic by physicians Dr Merriam said that the heart clinic in Framingham was going well, was doing a lot of good and was without objection from doctors

economics prepayment for medical care, group practice, and comprehensive service.

Gentlemen, if you will read proposal 4, lines 5, 6, 7 and 8, in them you will see that the co-operatives seek as late as 1949, when there are increasing signs of impending victory for our philosophy and methods, to strike you in an unguarded moment from your present vantage point. Truly our columnist Bill Cunningham painted a true picture, if we accept this proposal, when he wrote "We seem to have an exquisite genius for getting things fouled up past any explaining, understanding, or unraveling, and, generally, at the most inopportune times."

To clarify our position both philosophically and strategically, I offer the following amendment to be substituted for lines 7 and 8 of Proposal 4. It is based on ten years of experience across the country. It lets the co-operatives go their way while we go ours. But it certainly does not give them approval or a euphonious "encouragement." It states the position of the Society taken under Dr. Phippen, president, when White Cross Co-operative started in Massachusetts, the position followed in succession by Dr. Lanman and myself as chairman of the Massachusetts prepayment enterprise on advice of doctors from Washington, D. C., who were embroiled in the Supreme Court fiasco.

I move that, leaving intact lines 5 and 6 of Proposal 4, page 2, we amend lines 7 and 8 to read as follows:

sometimes offer their members adequate medical care. No such plan shall be obstructed in procuring enabling legislation. No physician participating in such a plan shall be denied, by reason of participation per se, (1) membership in established medical societies, (2) hospital-staff appointments dependent upon such society memberships, (3) consultation courtesies by nonparticipating physicians on the usual plane of ethical relationships.

If the common-sense policy enumerated herein had been followed by American medicine for the past ten years, we should not have landed in the courts. We should not be subject to tactics seeking to extract from us approval of consumer co-operatives, we should have been spared 80 per cent of our difficulties, and we should be today in a much better strategic position before the people of our country.

APPENDIX NO 5

COMMITTEE ON TAX-SUPPORTED MEDICAL CARE

As a result of conferences with Mr. Charles Dunn, attorney of the Massachusetts Medical Society, and study of the law covering veterans' services it was learned that the fees for veterans' services are fixed by the Commissioner and may be paid only in accordance with the Commissioner's regulations concerning prior authorization, emergency and so forth. The one exception to this is explained in the following quotation from a letter from Commissioner O'Day:

The city or town is granted the privilege of paying aid in addition to what the Commissioner may authorize. When this is done that increase must be borne entirely by the place of settlement. If there are extenuating circumstances in a case, and the city or town wishes to pay more than we have originally authorized, and they clarify the situation, I usually meet that situation by increasing our allowance, but this would not apply to medical expense. Medical expense is always considered separate from the budget that is allowed for support and care.

This part of the law gives the Commissioner the right to determine any amount which he considers proper and lawful. The question before you, I presume, is whether a city or town would not have the right to pay in addition to the schedule that I have set up, and to that I would say that they have that right, but any amount that they pay over and above our schedule would not be shared by the Commonwealth. I presume that there are some towns that will probably pay higher than my schedule, but if they do, the amount they pay in excess of my rate will have to be their responsibility.

After considering the above, two members of the Committee on Tax-Supported Medical Care conferred with Com-

missioner O'Day with the result that he is willing to change the directive to permit the following changes:

Note these changes, kindly refer to Page 2 of my Medical Directive. *Fee Schedule*

Home Visit change to \$4

Office Visit change to \$3

Below entitled *Night Calls* \$1 additional to \$2 additional and change time limitations from between 9 p.m. and 7 a.m.

The Committee on Tax-Supported Medical Care recommends to the Council that it approve the fees for veterans' services as recommended by the Commissioner of Veterans' Services for the present.

FREDERICK S. HOPKINS
FRANCIS P. MCCARTHY
FRANK W. SNOW
ALBERT A. HONOR, *Chairman*

APPENDIX NO 6

COMMITTEE ON LEGISLATION

The Legislative Committee has held several meetings during the year and has considered many bills of importance to medical practice. Our most important effort was directed toward the defeat of the chiropractor bill, which would have established a board of registration for chiropractors in the Commonwealth. This bill was heard before the public-health committees, and aside from our regular speakers several district presidents responded to our request and spoke in opposition.

Definite action was also taken on the vaccination, viro-section and open-hospital bills and on a bill to exempt the Blue Shield from taxation, and opposition was made to several bills proposing further legislation to allow future graduates of substandard medical schools to take examinations before the Board of Registration. Bills before the national Congress such as S5 are in the hands of the subcommittee on national legislation.

The committee believes that the physicians of the Commonwealth should present a united front in making recommendations to committees of the Legislature. This committee makes a careful study of all bills having important medical significance and arranges to make appearances before committees of the Legislature when they hear such bills. While it is the privilege of any individual to express himself at these hearings, it is confusing to the committees of the Legislature to have groups of physicians appearing on both sides of the same question. This committee will be glad to discuss proposed legislation with those who are to make appearances in order that they may understand the reasons for the position that this committee takes.

It has been suggested that a poll of the action of the legislators on important medical bills be published in the *New England Journal of Medicine*. It has been the opinion of this committee that such publicity is unwise because of its danger of antagonizing individual legislators to future bills in which we may have an interest. Such information is usually in the hands of the committee and may be obtained through the district legislative councilors.

The personal contact between physicians and their representatives in the General Court is the most important influence in guiding legislation and is of more importance than the formal appearance that we make at the State House. We urge that each district society arrange to have local physicians interest themselves in the work of their senators and representatives so that they may build up a friendly basis for the future discussion of important bills relating to the public health and the practice of medicine.

ALFRED L. DUNCOMBE
CURTIS C. TRIPP, *Co-chairman*

APPENDIX NO 7

SUBCOMMITTEE ON NATIONAL LEGISLATION

At a meeting on February 17, 1949 the available bills on health legislation were screened. It was voted to favor in principle:

(1) S 522 and similar bills for Local Health Units, provided the services were delineated, (2) HR 325 and

to state programs administered by state boards of health is an acceptable method of helping to meet this responsibility.

7 The medical care of those who are able to purchase it by voluntary prepayment plans or by direct payment is the responsibility of the individual.

8 The federal Government, should, whenever possible, support voluntary prepayment programs for hospital and medical care.

9 Eligibility for receiving benefits under a program aided by federal grants should be determined by the individual states or communities.

10 The patient shall have free choice of his physician, group of physicians, clinic or hospital from among those participating in any plan, provided that the physician, group of physicians, clinic or hospital shall have the right to refuse or accept the patient.

11 Physicians and other qualified persons rendering medical care shall receive adequate remuneration for their services.

12 The physician shall be free to elect or reject without prejudice participation in a medical care plan. The rights of the physician as to the choice of methods by which he is to be paid shall be fully protected.

13 We agree that the federal Government now should subsidize medical and nursing education, medical indigents, health and diagnostic centers, including mental, where not now adequate.

We believe effective organizations of state and district health councils would immeasurably improve the community concept of local health needs. The initiative of the people themselves, and especially of the medical and public-health personnel, must provide the spark.

14 The Massachusetts Medical Society looks upon these basic principles as essential to the development of any successful medical-care plan and, as guides by which to evaluate medical-care plans that may be proposed in the future, with the understanding that changing conditions may require their later revision.

We further urge that our delegates to the American Medical Association be instructed to press for the general adoption of the above principles and proposals by the American Medical Association.

HAROLD R. KURTH
ELMER S. BAGNALL

APPENDIX NO. 4

REMARKS OF DR. MCCANN

By and large, the adoption of these wholly admirable provisions, except for one of them, will place us in a proper and enlightened position toward the Government and the public.

I question the propriety of Proposal No. 4, page 2, lines 5, 6, 7 and 8, which by description of a consumer co-operative mechanism and by use of the word "encourage" in line 8 would maneuver us into what is tantamount to public approval of the consumer co-operative movement. I think we should take some stand concerning it, but not to give encouragement or approval.

The composite memory of any group such as the Council reminds me of an old knife thrown into the corner of a drawer—it gets rusty, loses its edge and does not cut well any longer. However, there are those of us who have served you for ten long years on the firing line in medical economics, whose memories have been kept keenly sharpened while laboring in the field of prepaid medical care.

Why, with Proposal 4 should the Massachusetts Medical Society give approval to the consumer co-operative movement in medicine? With meaningless provisos about advisory medical committees (shades of the Wagner-Murray-Dingell Bill) our profession would be subordinated in such organizations to the bargain-seeking propensities and controls of the lay consumer groups on their own strict terms, or to self-appointed medical managers who probably would be less desirable to bargain with.

The consumer co-operative record is not beyond scrutiny. Their philosophy is essentially that of socialism, although called euphemistically economic democracy, with the organized consumer group dominating and controlling the private medical entrepreneur directly rather than indirectly

through governmental agencies. Their record is not unimpeachable. Their business projects are strewn with the story of use of all the devices ascribed to *laissez-faire* capitalism: price-cutting, tie-in-sales, misrepresentation, monopoly practices—by putting private enterprise out of business. They have used monopoly to break monopoly and then continue themselves to monopolize.

The co-operative's achievements on health matters should be carefully scrutinized.

The White Cross of Massachusetts, after much fanfare and publicity, enrolled a few thousand subscribers, paid doctors 13 cents on the dollar, and then folded up because their fly-white idealists had left for the wars. What the color was of the other boys who went to wars, or of us who stayed behind, I have never found out. Several leaders of this defunct White Cross are on public record in support of compulsory health insurance. One should watch this trend as the record unfolds.

The Group Health Co-operative of Washington, D. C., after many long years finally reports an enrollment of the magnificent total of 24,000 subscribers; there is available their growing list of exclusions and restrictions of services; there is the record of continued use of it by those in the most satisfactory income brackets. A post-mortem examination in this case when it comes will be an interesting study on the anatomy of failure. Of course, under the leadership of Harry Becker, of which more later, they will support compulsory health insurance.

In New York City with the help of considerable endowment, HIP for the moment has had some measure of success under Dr. Dean Clark, who recently came to our hospitable shores, and who, while in the Public Health Service, is said on qualified authority to have been quite sympathetic to compulsory health insurance.

The small co-operative at Elk City, Oklahoma, under Dr. Shadid, is shown by accountant studies to be kept solvent in large measure by the payment for service in the traditional manner, by large numbers of nonmembers from the surrounding areas who use these facilities. Presumably Dr. Shadid and Harry Becker, incorporators and directors of the Co-operative Health Federation of America, subscribed to the unanimously adopted resolution from the parent organization, the Co-operative League of the United States of America, which was presented by a Mr. Hansen to a Congressional Committee September 9-11, 1946. The resolution read in part:

To this end it supports nationwide health insurance under public auspices, provided that any proposed government action in this field provided for the continued expansion of volunteer co-operative health and medical care plans—and the making of Federal loans to consumer sponsored groups for hospitals, clinics and equipment.

The whole medical co-operative philosophy and movement seems to have stemmed from Michael Davis, the presiding genius over the drive for compulsory health insurance from his lesser shadow, veterinarian Nathan Sinae, who aided and abetted the effort to install compulsory health insurance in Hawaii before it should achieve statehood, from Kingsley and Boas, who currently seem to be striving for control of a segment of the New York Medical Society with extravagant promises of things to come—and who of course support compulsory health insurance, and from a charming feminine agent of a Detroit automobile union, who a few years ago challenged me with the startling and arresting words spoken in a strange, unrecognizable, guttural accent, not indigenous to any part of America, at a conference in Ann Arbor sponsored by Michael Davis and his veterinarian Nathan Sinae, "How dare you talk such individualism when we all know that America and the rest of the world is going collectivist!"

As a physician steeped with some others in a modest but real achievement in construction of a multi-million dollar prepayment enterprise, as one who was trained in group medical practice, as one who has practiced both on a group and an individual basis as one who has studied and written medical care contracts based on sound actuarial and labor-management-professional background, I charge that it is time to discredit the unrealistic, fantastic, ideologic shibboleth of the co-operatives that all at once we must throw together, as a blanket to cover the face of our diversified America, the three debatable facets of current medical

mittee and ordered to make restitution to the patient. This case is of interest because it is a repetition of a similar episode in which he was concerned a few years ago. The case is placed on file pending his future conduct.

In the cases of fellow against fellow, all but one of those accused were found guilty, reprimanded by the committee and requested to apologize to the offended brother. These cases were considered closed. In the remaining case, the offending fellow, while not found actually guilty of any infraction of our code of ethics, was adjudged guilty of conduct unbecoming a gentleman and a member of the Massachusetts Medical Society. A letter of severe admonition was sent to him, and his case was placed on file pending his future conduct.

The requests for information regarding ethical procedure varied from information concerning advertising, procedure in appearances in court and also procedures that involved public relations. In general, the advice was given by the chairman and approved by the Committee at the following meeting.

In furtherance of the interest shown by the Society in better public relations between the laity, the press and the medical society, every request for advice on matters pertaining thereto has been given special consideration by the Committee on Ethics and Discipline.

It was with that thought in mind that the Committee approved of the code of ethical conduct sponsored by the Eye and Ear Infirmary of the Massachusetts General Hospital, recently. The Council, at its meeting on February 2, 1949, returned approval of the code to the committee for reconsideration. This matter was discussed at the meeting of the Committee on Ethics and Discipline on February 16, and the committee unanimously reaffirmed its approval of the code of the Eye and Ear Infirmary as printed on page 2 of the circular of advance information to councilors, in advance of the Council meeting on February 2, 1949.

APPENDIX NO 11

COMMITTEE ON MEDICAL EDUCATION

In accordance with your request, the Committee on Medical Education has communicated with the deans of the three medical schools in Boston and asked them to nominate a fourth-year student to receive the Massachusetts Medical Society prize.

We requested the deans to nominate a student "who best exemplifies those intangible qualities which serve to designate him as the good physician."

The nominations from the deans were as follows:

Boston University — Sylvan B. Baer
Harvard University — Henry S. Harvey
Tufts College — William H. Ellswood

The Committee, therefore, recommends that these nominations be seconded and approved.

JAMES M. FAULKNER
GEORGE D. HENDERSON
ISAAC R. JAVELSON
ROBERT I. MONROE
CHESTER S. KEEFER, *Chairman*

APPENDIX NO 12

ADVISORY SUBCOMMITTEE ON MEDICAL EDUCATION

The following letter from Herbert I. Harris, M.D., and a mimeographed copy of a progress report to the membership of the Massachusetts Society of Clinical Psychologists

from the committee on licensing and certificates of psychologists was referred to this subcommittee for consideration.

Dr. H. Quimby Gallupe
Secretary, Massachusetts Medical Society
8 Fenway
Boston, Massachusetts

Dear Dr. Gallupe:

I enclose for your consideration a progress report of the Massachusetts Society of Clinical Psychologists which is self-explanatory.

It has occurred to me that the present-day interest in the activities of clinical psychologists is such that our Society should be very much aware of what the ethical clinical psychologists are attempting to accomplish in obtaining certification. All those ethical clinical psychologists with whom I have had occasion to talk are agreed that they desire to (a) prohibit the private practice of psychotherapy by clinical psychologists and (b) when clinical psychologists attempt psychotherapy, to insure that adequate psychiatric and medical safeguards and provisions have been provided. You will notice that in this progress report no mention of the exact nature of what the clinical psychologists plan to do in practice is set forth.

It seems to me that the Medical Society would be of considerable help to the ethical clinical psychologists in making sure that a fairly watertight certification law be established, in such fashion that the measures I have outlined above will be included, and that clinical psychologists who are ethical and do wish to work with and under the supervision of psychiatrists have that opportunity.

I am sure you are aware of the fact that many emotional disorders which independent clinical psychologists might attempt to treat often mask an underlying physical disorder, which can on occasion be extremely grave.

I should very much appreciate your views on this entire matter and stand ready to be of any assistance I can to your Legal Committee.

(Signed) HERBERT I. HARRIS, M.D.

20 Lowell Street
Cambridge, Massachusetts

An analysis of the preliminary report shows that 70 per cent of the members of the Massachusetts Society of Clinical Psychologists voted for certification of clinical psychologists by this state on a state level. They are fully aware of the necessity of high standards for such certification and the desirability of uniform legislation in the various states.

From other data available to this subcommittee it appears that the states of Virginia and Connecticut are certifying clinical psychologists and all psychologists respectively. Recently Kentucky passed a law, but because of certain ambiguities in it, it is not certain whether the law provides for certification or licensing of clinical psychologists. Legislation along these lines is pending in New Jersey and the District of Columbia. An attempt is now being made in Virginia to amend the law in favor of licensing clinical psychologists.

It becomes obvious that uniform legislation in all states is impossible, and therefore the standards of training and experience may vary a great deal in the various states.

For approximately two years committees of at least two national psychiatric societies have been deliberating upon the relation between psychiatrists and psychologists in general and clinical psychologists in particular. These committees are likewise considering ways and means to certify or license clinical psychologists on a national basis. To the best of our knowledge no constructive proposals have been made so far. In the meantime, as mentioned above, three states have passed laws to certify or license clinical psychologists and one other state and the District of Columbia are contemplating similar legislation.

Within the framework of the Council on Medical Education of the American Medical Association there are well established precedents for certification, on a national basis, of medical specialties and various other professions allied to the practice of medicine. Such boards of certification exist for surgery, internal medicine, neurology, psychiatry and so forth and for medical technologists, x-ray technicians

similar bills for Hospital Construction, (3) HR 1779 Scholarship Loans to Medical Students, provided the enactment was placed under the Surgeon General of the Public Health Service instead of the Department of Education, and (4) HR 12 and similar bills for a National Science Foundation. It was considered that the several bills relating to cancer, arthritis, and multiple sclerosis could be best handled under a National Science Foundation rather than enacted individually.

It was voted to oppose (1) S 5 and all bills dealing with compulsory health insurance, (2) HR 1512 Chiropractors in Veterans Administration, and (3) HR 1570 Health of School Children in its present form. In regard to establishing a Secretary of Health, Education, and Security (HR 184 and HR 782) it was considered that a single secretary of health as advocated by the American Medical Association was preferable, but, if this goal proved unobtainable, HR 184 was favored provided that the under-secretary of health was a physician, and HR 782 was opposed.

VLADO A. GETTING
CHARLES G. HAYDEN
DONALD MUNRO
AUGUSTUS THORNDIKE
ELMER S. BAGNALL, *Chairman*

APPENDIX NO 8

COMMITTEE ON PUBLICATIONS

The Committee wishes to report on the publication of *The New England Journal of Medicine* for the year 1948. The year was marked in all parts of the country by difficulties in the publication of medical journals. Costs have increased, and the revenue from advertising decreased. A majority of the state journals suffered a drop in income from advertisements procured through the Cooperative Medical Advertising Bureau of Chicago. *The New England Journal of Medicine*, however, experienced an increase of 23.8 per cent from this source. The cost of paper rose from \$11.55 per cwt to \$12.60. A new contract for paper at this rate was signed in September, with assurance of benefit of any drop in the general price of paper. The printing contract for 1949 was renewed at the 1948 rate, subject to renegotiation in the event of another increase in printers' wages.

General expenses for 1948 were \$269,018 — an increase of \$28,388 over 1947. The Pension Fund and Social Security taxes account for approximately \$6500 of this amount — and the fact that there were 53 publication dates in 1948 in contrast to the usual 52 added \$3500 to the cost of publication.

Revenue in 1948 was \$267,101 (in addition to which \$5000 was received from the Society) — an increase of \$27,553 over 1947. The net loss for the year 1948 was \$1,916.18.

The total circulation as of the end of December, 1948, was 24,770. The breakdown of this figure is as follows:

Regular subscribers	14,266
Student subscribers	3,725
Massachusetts Medical Society	5,942
New Hampshire Medical Society, once a-month	292
New Hampshire Medical Society "regular"	223
Exchanges	193
Complimentary	59
Advertisers	70
Total	24,770

During the year 1948 the Editorial Board considered 352 manuscripts, of which 170, or 48 per cent, were accepted. This was 46 more manuscripts than in 1947, when 64 per cent were accepted. This indicates a healthy condition and allows greater discrimination in the selection of articles for publication.

The accounts for the year have been audited by Hartshorn and Walter, and a copy of their report is on file in the Treasurer's office. An abstract of the report is appended.

Because of the uncertainty in costs of publication, the Committee requested an appropriation from the Society of \$10,000 for the year 1949, which was included in the budget adopted by the Council at its meeting on February 2, 1949.

Dr. Garland has now been editor of the *Journal* for a full year. His conduct of its affairs has more than justified the confidence in him that was felt at the time of his appointment and augurs well for the future.

The secretary of the Society informs us that there is urgent need for a new Directory. Money for its publication was included in the budget adopted by the Council on February 2, 1949. We recommend that the Council order the publication of a Directory of the Officers and Fellows.

As you will see from the program of this meeting, the Shattuck Lecture will be delivered by Dr. Paul Dudley White, of Boston.

Miscellaneous	2,878.57
Total	\$267,101.97
Net loss to Massachusetts Medical Society	\$1,916.18

APPENDIX NO 9

COMMITTEE ON ARRANGEMENTS

The program that the Committee presents for the annual meeting is essentially its final report, since it represents the results of our work during the past year.

It is gratifying that so many of our members from the central and western parts of the State have consented to participate in the scientific program. To all these gentlemen, as well as to those who are coming to us from a distance, the Committee extends its thanks.

We again acknowledge the co-operation of the Worcester District Medical Society, whose attention to innumerable details of arrangement that do not appear on the surface but are essential for success has been of inestimable help.

Members of the Society are reminded that the commercial exhibits are the principal source of income for the annual meetings and are urged to visit them frequently.

FRANKLIN G. BALCH, JR.
GORDON DONALDSON
ALBERT EHRENFRIED
JOHN W. NORCROSS
HAROLD G. GIDDINGS, *Chairman*

APPENDIX NO 10

COMMITTEE ON ETHICS AND DISCIPLINE

The "deadline" for submission of the annual report of the Committee on Ethics and Discipline necessitates an incomplete summary of our labors. At the present time, 3 cases of a rather serious nature are being investigated, formal action to be taken later.

The work of the Committee during the year has been concerned with the usual list of complaints against doctors for suspected improper treatment of cases, complaints of fellow against fellow of violation of the code of ethics and requests for guidance in ethical procedure. Of the complaints against fellows by laymen, all but one was decided in favor of the fellow concerned. In this isolated case, the fellow was found guilty of unethical conduct, was reprimanded by the Com-

of Nutrition in Health and recommends that greater emphasis be placed on education in this subject on the undergraduate and graduate medical levels." It is desired that this motion be brought to the attention of the Council for its information.

After considerable and prolonged discussion, the Committee adopted a motion as follows:

It is the opinion of the Committee that pilot clinics should be held in pivotal localities throughout the State to offer, on a voluntary basis, health examinations under the auspices of district medical societies in co-operation with the community hospital and other interested groups. The findings of these examinations, it is recommended, would be referred to the family physician. This committee further recommends that a subcommittee of the Committee on Public Health be appointed to carry out this program, that this subcommittee be made up of one representative from each district and that this subcommittee have power to act. It is the desire of this committee that this motion be presented to the Council for action at the next meeting.

The Committee also recommends that the Council adopt the following resolution: "That positive efforts toward the establishment of local health unions and health centers be actively supported by the individual members of the Massachusetts Medical Society."

The Committee also passed the following resolution: "Whereas the Massachusetts Medical Society has already approved an attempt to find the undiagnosed diabetic patients of the Commonwealth and bring them under treatment, and whereas representatives of a large number of industries in the state have expressed a desire to co-operate with efforts directed at the discovery of latent diabetes in order to secure early treatment, be it resolved that the Council of the Massachusetts Medical Society recommend suitable action by the officers and committees of the district medical societies to carry out such programs aimed at the discovery of diabetes in the community consistent with the Diabetes Detection Program and Diabetes Week sponsored by the American Diabetes Association."

It is requested that you bring this resolution to the attention of the Council for action. It is our understanding that a similar resolution will be adopted for Council action by the Committee on Industrial Medicine and by the Committee on Diabetes. We believe it is Dr. Root's desire that this resolution be presented to the Council as a joint resolve of the three committees.

JOHN J. POUTAS
WARREN R. Sisson
LAWRENCE J. SMITH
CONRAD WESSELHOEFF
ROY J. WARD, *Chairman*

APPENDIX NO 14

HEALTH-PROTECTION CLINICS

It is the desire of all voluntary health agencies of the medical, dental, nursing and hospital professions, of the hospitals and of the official health agencies to make available to all people every essential diagnostic, therapeutic and preventive measure of high quality. In recent years various screening techniques have been made available for determining the probable presence or absence of a certain disease, such as diabetes, cancer, syphilis or tuberculosis.

Health agencies have been screening the public through clinics designed primarily for the application of one or, at the most, two of these procedures. It is our opinion that we are not making available to as many of the public as possible the composite benefits of all the screening techniques applied at a single visit. It is possible to make these screening techniques available as well as a reasonably good history and physical examination in a single visit to a health-protection clinic. The application of these screening devices in a single visit would not be subject to the same error that is now inherent in most of our screening programs — namely, that we screen the patient for one or more types of illness, thereby giving him a false sense of security in believing that

he may be free from all other illnesses. This clinic would screen be patient for all illnesses for which we have an acceptable technique and, in addition, give him the benefit of having a history taken, a physical examination and a personal conference with a physician concerning further steps that he should take to safeguard his health.

Many voluntary health agencies, the professions engaged in the healing arts, voluntary hospitals and public-spirited citizens have become concerned about arguments raised by the proponents of socialized medicine that many people are not afforded proper medical care. The availability of these health-protection clinics would, in our opinion, provide an opportunity for private enterprise in co-operation with the Department of Public Health to make available to meet this apparent need of people who cannot otherwise afford to obtain health protection for themselves.

These clinics are for the purpose of finding the presence or absence of certain major illnesses that are some of the leading causes of death. The objective of the clinic is to examine persons referred by the family physician, clinics or other social agencies, by applying screening procedures, giving a physical examination and performing certain laboratory tests that would assure the person of his apparent good health. The clinic visit would be terminated by a personal conference with a physician who would instruct him about the proper follow-up study, including visits to his family physician or clinic if he cannot afford the former and obtaining the name of a physician to whom the final report will be sent. For certain health-protection purposes such as dietary supervision for overweight or in case of diabetes, follow-up services would be offered at the request of the family physician, or if there were no family physician at the request of the clinic or other group caring for the patient.

This co-operative project between the medical profession, the voluntary hospitals, the cancer, tuberculosis, diabetic and heart voluntary associations and others would depend upon the following factors:

The organization of a central guiding committee, which would elect an administrator who would be responsible for the operation of the program.

Mutual sponsorship of such a program by the various groups who would participate both financially and in the promotion of the program.

The development of a plan for the opening of a demonstration health-protection clinic, which might be used as a guide for developing others throughout the Commonwealth.

The establishment of a plan and budget for the maintenance of this clinic by the sponsoring agencies under the direction of the administrator whom they would select.

Direction of the public-relations program by the administrator and joint participation by all the agencies concerned. (In order to be effective, the program must be well publicized to the professions concerned as well as to the public.)

It is suggested that no charge be made for services rendered except that persons who are processed through the clinic might, if they wish, contribute to the support of the clinic any amount that they were able to pay up to the actual cost of the services rendered. All such funds would accrue to the advancement of the clinic and not to the participating agencies sponsoring it.

The Department of Public Health would not control this clinic in any fashion other than by licensing, but would be one of the sponsoring agencies.

The data collected at the clinic should be available to all the sponsoring agencies for scientific analysis but the identity of patients processed in the clinic would be kept confidential and not made available to any of the sponsoring agencies.

It is the objective of the Department to present this proposed health-protection clinic to a group of agencies and individuals in the Commonwealth who may be interested in making available to the people of the Commonwealth these services. We believe that through these services which would include a history, a physical examination, an x-ray film of the chest, a blood test and a Papanicolaou test for vaginal smears, we should be able to screen the presence of the major killers — namely, heart disease, cancer, diabetes, tuberculosis, nephritis and

medical librarians and others. They maintain high standards of education, training and experience for certification in their respective fields. A similar technic for certification of clinical psychologists would establish a uniformly high standard throughout the country. We suggest that such board should be under the guidance of the American Board of Neurology and Psychiatry and function with the approval of the Council on Medical Education of the American Medical Association.

We therefore recommend that

1 Certification of clinical psychologists by the American Board of Neurology and Psychiatry be approved. Certification by the State is disapproved.

2 Licensure by the State to practice clinical psychology is not supported by us at this time.

One member of this subcommittee, Dr. George E. Gardner, dissented from the above recommendations and will submit an alternate recommendation.

C. GUY LANE
DONALD A. NICKERSON
AUGUSTUS THORNDIKE
I. R. JANNESEN, *Chairman*

MINORITY REPORT OF ADVISORY SUBCOMMITTEE ON MEDICAL EDUCATION

This problem of licensure and certification is a very complex one, and I might say that it is one that at the present moment is engaging the attention of numerous professional committees at the national level. For example:

1 There is a committee of the American Psychiatric Association called the Committee on the Relation of Psychiatry with Psychology. This committee at the present time is wrestling with this very problem of the training of the clinical psychologist, the function, with a view of emerging eventually with some suggestions regarding the ticklish problem of certification or licensure. In doing this it is working in close collaboration—in joint committee meetings, to be exact—with the Committee of the American Psychological Association on the relation of psychology with psychiatry. The memberships of both these committees are representative of the two disciplines, and the results of their work are being awaited by both groups.

2 There is also a committee at the national level—namely, the Committee on Clinical Psychology of the Group for the Advancement of Psychiatry—that is endeavoring to establish in collaboration with representatives from the American Psychological Association some fixed standards of training, Ph.D. requirements, experience and supervision and so forth that will be satisfactory not only to the psychiatrists but also to the psychologists. This committee is turning its attention to the very pressing problem of licensure and certification and is also not out of touch with the work of the committees noted above.

3 The psychologists themselves, through the recent establishment of their Board of Examiners for Professional Psychologists, have put through and are now enforcing rigorous standards for certification as a diplomate in clinical psychology. This in itself all assume to be a step in the right direction toward a national worthwhile plan.

4 And, finally, only yesterday Dr. Dael Wolfe, executive secretary of the American Psychological Association in Washington, through communications to me by way of Dr. William Menninger, president of the American Psychiatric Association, has called for a representative from psychiatry, together with representatives from the other disciplines involved, to meet together in a few weeks to definitely take steps to establish a uniform national procedure of certification of clinical psychologists—all psychologists in whatever capacity they may work directly with the public.

I have gone into the various steps taken by these various interested bodies of professional people so that it will be clear that there is at present much work being done toward a solution of this very important problem, and

it seems to me that it would be much less precipitate if we at the local level should await the results and possibly the accepted program of the people working in the fields most affected. I say we should do this rather than put forth a statement that we favor any such thing as certification by the American Medical Association, its Council, or the Board of Neurology and Psychiatry and so forth. This whole problem of the function and role of the clinical psychologist is too complex to be settled merely by stating that these people (over 5000 of them as a matter of fact—most of whom have Ph.D. degrees) are to be considered “adjuncts to the medical profession” and thus to be classified and certified as technologists, technicians and librarians. The work of the psychiatrists on the above committees during the past two and a half years has convinced them that no such simple solution would suffice.

Therefore, in the light of the above, I suggest, that our committee go on record as stating:

In view of the fact that well accredited bodies and committees of psychiatrists sponsored by their national professional organizations, working in close collaboration with representatives of the American Psychological Association, are at this time endeavoring to establish a nation-wide policy of certification and licensure of clinical psychologists, it is the opinion of this committee that any and all such steps toward licensure and certification at the state level in Massachusetts should await the results and suggestions relating to licensure and certification on a national level. While awaiting these programs, we are opposed to licensure and certification at the state level, feeling that such a plan would be premature, or inadequately formulated, or both.

I hope that some of these data will help clarify the issues for us, but if you and the rest of the committee feel that you do wish to go on record in the matter as outlined on Page 2 of your report referable to certification, may I ask you if you will omit my name from those of the committee who agree with these proposals. If my name were to be forwarded at all in connection with such proposals, I would like to have you list me as “dissenting,” and if possible for the reasons outlined above.

GEORGE E. GARDNER

APPENDIX NO. 13

COMMITTEE ON PUBLIC HEALTH

The Public Health Committee at its November 15 meeting heard a presentation by Dr. Monroe of certain problems with respect to the care of the aged. The Committee at its March 2 meeting endorsed once again the program of Dr. Monroe and voted that this endorsement be brought to the attention of the Council. Dr. Monroe's discussion before the Committee was as follows. He pointed out that of the approximately 100,000 persons in this state over age sixty-five, a third were independent and working, a third were independent owing to insurance, and a third were dependent upon charity of one type or another, or some form of social security. He stressed the need for improving the professional standards in so-called nursing homes and boarding homes. He described to the Committee his model home for the aged, which would include such services as employment, rehabilitation, teaching, recreation, preventive medicine, and even the provision of part-time house-keeping to the aged persons in their own homes.

At its November 15 meeting the Committee also adopted the following motion, which, it voted at its March 2 meeting, should be brought to the attention of the Council: “This committee endorses in principle the limited investigation of the use of BCG vaccine in tuberculosis contact families in certain districts of Boston by the Tuberculosis Division of the Boston Health Department in collaboration with the U. S. Public Health Service and the State Health Department subject to the approval of the Massachusetts State Department of Health.”

At its March 2 meeting the Committee adopted the following motion: “This Committee recognizes the importance

or much of their time to industrial medicine. The qualifications for membership are the same as those in the parent association. Here again are many physicians doing some industrial medicine who are not members of the Conference.

The Boston Branch of the New England Association of Industrial Nurses is a component society of the American Association of Industrial Nurses, a very flourishing and active though relatively young organization designed for the development and professional advancement of nurses working in industry. Some of our colleges that conduct schools of nursing include industrial nursing as an important part of the curriculum and provide in-plant training.

It is apparent, therefore, that industrial medicine and industrial nursing have become an important department in both professions.

A recent survey made by the Division of Occupational Hygiene of the Commonwealth of Massachusetts in 654 industries employing 398,800 persons reveals the following information:

Number of physicians employed full time	19
Number of physicians employed part time	159
Number of physicians employed on call	416
Total	594
Number of nurses	829

As you are not unaware, organized labor has become concerned about the health of its members and many of them are now including medical service in their negotiable contracts. That is true especially in the United Mine Workers organizations, the Garment Workers Union, the power companies, the automobile industries and others.

As previously reported, the seventy-ninth Congress enacted legislation establishing a Federal Employees Health Service which is a further recognition of the importance of industrial medicine. Units have been recommended for Boston by the United States Public Health Service but have not yet been organized.

Stimulated by workmen's compensation legislation for industrial accident and diseases to some degree the large industries and businesses throughout the Commonwealth are now providing a quite satisfactory medical service or health-maintenance program for their employees. As in every phase of medical practice, there is room for improvement in some of these services especially when employed nurses are not under responsible medical supervision.

It has been very difficult to introduce worthwhile health-maintenance programs in small industries. There are several reasons for this, among them fear of the cost, the uncertain economic outlook in the country, the uncertain demands from labor and a lack of medical men properly trained in industrial medicine. We are advised by the American Medical Association, Council of Industrial Health that this condition exists all over the country and presents a challenge that nobody has yet been able to meet successfully. It will continue to be a problem for the earnest endeavor of this committee to solve with the help of other interested groups.

This committee wishes to recommend the adoption by the Council of the resolution submitted by the chairman of the Committee on Diabetes, which is a joint resolution by that Committee, the Committee on Public Health and the Committee on Industrial Health, for the detection of the patients with unrecognized diabetes in industry and in the community.

This committee also wishes to present the following resolution:

Whereas, industrial medicine has become an important part of the American Medical Association's Program for the Advancement of Medicine and Public Health and is being favorably considered by the Association for specialty status,

Be it resolved, that the Council of the Massachusetts Medical Society establish a section on industrial health so that this phase of practice may participate in the annual meetings of the Society with the other sections of the Society.

APPENDIX NO 18

COMMITTEE TO MEET WITH THE MASSACHUSETTS HOSPITAL ASSOCIATION

Last December, in response to many inquiries at the office of the Secretary as to the acceptance and degree of success of the Gallupe Plan previously approved by the Society, a questionnaire was sent each hospital in the Commonwealth through the office of each district secretary. All hospitals were included whether approved or not, private or public, large or small. The questions asked were:

1. Did or did not co-operate in the promotion of the Gallupe Plan?
2. To what extent?
3. How has it worked?
4. Have you any physicians on either the regular, courtesy, or supervised courtesy staffs who are graduates of unapproved schools?
5. How many?
6. How many have you accepted under the Gallupe Plan?
7. If nothing was done, why not?
8. Remarks.

Replies were received from 55 hospitals in 15 districts having a total bed capacity of approximately 7800. No state, federal or teaching hospital associated with a medical school participated. Twenty-seven, or approximately 50 per cent, have replied that they were co-operating in the promotion of the Gallupe Plan, and reported a total of 194 graduates of unapproved medical schools on their supervised courtesy staffs. All reported that the plan was working "well or satisfactorily." None reported unfavorably. Some complained of the time and effort required of the staff men who did the supervising. In some cases certain men have been promoted to the regular courtesy staff on the basis of their work and interest. Thirty-six hospitals reported a total of 270 graduates of unapproved schools on their combined staffs—usually the supervised courtesy staff. The largest number reported by any one hospital was 68, whereas others reported 27, 15, 15, 15 and 15 respectively.

The reasons most commonly given for not participating in the operation of the Gallupe Plan were staff regulations, scarcity of beds, which prevented acceptance of all physicians of approved schools who had made application, many small hospitals in rural areas reported no demand from graduates of unapproved schools.

Even though the percentage of questionnaires returned is small, from the information given, by the hospitals where the plan is in operation, it appears that it has real merit, that the men selected have greatly appreciated the opportunity given them, and that the postgraduate teaching from clinics, staff meetings and supervised care of patients has helped make better physicians of these men who graduated from unapproved medical schools. We hope the plan will be adopted more generally.

EDWARD A. ADAMS

APPENDIX NO 19

COMMITTEE ON MATERNAL WELFARE

During 1948 two meetings were held on February 17 and November 16. The following members of the Committee were present at one or both of these meetings: Raymond S. Titus, M.D., Arthur F. G. Edgelow, M.D., Richard P. MacKnight, M.D., Robert L. DeNormandie, M.D., and David D. Rutstein, M.D., Arthur Hertig, M.D., and Miss Alice G. MacKinnon, R.N., were guests.

In co-operation with the Committee on Maternal and Child Welfare of the Department of Public Health, Common-

hypertension — and other conditions that may lead to serious protracted illness, or disability, or even death

VLADO A. GETTING
Massachusetts Commissioner of Public Health

APPENDIX NO 15

COMMITTEE ON MEDICAL DEFENSE

Malpractice cases carried over from 1947	9
Cases disposed of in 1948	5
New cases in 1948	6
Cases pending as of January 1 1949	10
Legal expenses 1948	\$3,730 00
Other expenses	None

The unusually large expenditure resulted from 2 cases that together cost \$2184 33 (\$1186 76 and \$997 57). The first took a month in Superior Court, resulted in a verdict for the doctor and has been carried to the Supreme Court on appeal by the plaintiff. The second was primarily defended by an insurance-company attorney, but the Society also filed its own brief because of the importance of the questions involved. Trial resulted in a verdict against the doctor, but the Society was reassured by the court's statement that "Nothing contained herein need cause anxiety to an honest physician who administers narcotics to a patient in accordance with the prevailing standards of medical practice."

Although it is unlikely that such important demands will be made on this committee in 1949, it has still been thought advisable to increase the budget from \$1500 00 to \$2000 00 in order to give the treasurer a fairer picture of what can happen. This has been done, and it is the hope of the Committee that the increase will be returned unused at the end of the year.

APPENDIX NO 16

COMMITTEE ON SOCIETY HEADQUARTERS

It is obvious that the present quarters of the Massachusetts Medical Society are not adequate for its purposes, and this committee has failed to obtain the building next to the Boston Medical Library.

There is an opportunity for the Massachusetts Medical Society to unite with the Boston Museum of Science, which has recently bought six acres of land in Boston on which to construct a new museum. The museum will include a planetarium and a Hall of Man.

On March 25, 1949, a meeting of the Committee on Society Headquarters was held. Present at this meeting, besides the members of the Committee, were Dr. Reardon, president, Dr. Gallupe, secretary, and Mr. Robert Boyd, executive secretary of the Massachusetts Medical Society. At this meeting, it was decided to ask the Executive Council of the Society for authority to explore the possibility of obtaining headquarters for the Massachusetts Medical Society, the Boston Medical Library, and the *New England Journal of Medicine* and to report its findings at a future meeting of the Council.

It may be possible, if we find it feasible, to unite with the Boston Museum of Science. This would give the Massachusetts Medical Society the opportunity to establish better public relations and to enhance the value of the doctor to his patient.

ALBERT A. HORNOR

WALTER G. PHIPPEN
GEORGE L. STEELE
FRANK R. OBER, *Chairman*

APPENDIX NO 17

COMMITTEE ON INDUSTRIAL HEALTH

The inclusion by the American Medical Association in its program for the advancement of medicine and public health of a section devoted to industrial medicine is evidence, in our opinion, of the importance with which the House of Delegates of the Association now regards this specialty and a recognition, at long last, that industrial medicine, once an outcast and later the tolerated stepchild of the profession, has attained full status and dignity because of the indisputably valuable contribution it has made to the health and welfare of the largest segment of the nation's population in peace and in war and by reason of the professional character, integrity and standing of the men who nurtured and developed it over the last quarter of a century and overcame many obstacles by meritorious performance.

Section No 11 of the American Medical Association's program is captioned "Industrial Medicine" and proposes, "Greater emphasis on the program of industrial medicine, with increased safeguards against industrial hazards and prevention of accidents occurring on the highway, home and on the farm."

Of course this program requires the talent and the aid of many ancillary services, of nurses and technicians, safety and mechanical engineers, chemists and physicists and so forth, but all these must be, as in the past, correlated and guided by the physician in industry whose concern is the health and well-being of people at work.

This program also requires the optimum of help and cooperation from the family physician and the surgeon to the end that the disabled worker may be restored to working capacity as fully and as promptly as possible.

It must be perfectly obvious that if our nation is to survive indivisible with liberty and freedom for all and at the same time carry on its back indefinitely more than sixty war-damaged or sick foreign countries it can be done only through sustained and increasing and efficient production of goods and services.

Such an achievement is unlikely in the event of any important breakdown in our nation's industrial health. It is, therefore, the job of industrial medicine working with the public-health and related services at all levels to endeavor to maintain the health of this nation's 60,000,000 working people and their families at a high level.

It should be unnecessary but it may be important to make it crystal clear at this point that industrial medicine is basically preventive medicine or health maintenance, a determined effort to keep well people well, and able and willing to work. Except in areas isolated from good medical care, in emergencies or other necessitous circumstances or legal edict, industrial medicine has no intention or desire to enter into the field of curative medicine.

In recent years our medical schools have taken cognizance of the importance of industrial medicine, and many of them have established postgraduate courses in industrial medicine. Because of its increasing importance it should, however, have its place in the undergraduate curriculum.

At the present time the American Medical Association is giving favorable consideration to recognition of industrial medicine as a specialty equal to surgery, internal medicine, neurology and so forth. To this end fellowships and residencies in industrial medicine are being established. The American Association of Industrial Physicians and Surgeons has sponsored such a fellowship at the University of Pittsburgh, and General Motors Corporation has established several in-plant residencies for training.

The American Association of Industrial Physicians and Surgeons now comprises upward of 2000 members, nearly all in this country. These are physicians who must devote full time or at least 50 per cent of their time to industrial medicine, must have so performed for five years and must belong to their local medical society to qualify for membership.

Across the country many more physicians engaged in industrial work full time or part time who are not members of the Association are unable to meet the qualifications or from choice.

The local component society of the national association, the New England Conference of Industrial Physicians and Surgeons, includes approximately 150 physicians in this area, chiefly in Massachusetts and Rhode Island, who devote all

or much of their time to industrial medicine. The qualifications for membership are the same as those in the parent association. Here again are many physicians doing some industrial medicine who are not members of the Conference.

The Boston Branch of the New England Association of Industrial Nurses is a component society of the American Association of Industrial Nurses, a very flourishing and active though relatively young organization designed for the development and professional advancement of nurses working in industry. Some of our colleges that conduct schools of nursing include industrial nursing as an important part of the curriculum and provide in-plant training.

It is apparent, therefore, that industrial medicine and industrial nursing have become an important department in both professions.

A recent survey made by the Division of Occupational Hygiene of the Commonwealth of Massachusetts in 654 industries employing 398,800 persons reveals the following information:

Number of physicians employed full time	19
Number of physicians employed part time	159
Number of physicians employed on call	416
Total	594
Number of nurses	829

As you are not unaware, organized labor has become concerned about the health of its members and many of them are now including medical service in their negotiable contracts. That is true especially in the United Mine Workers organizations, the Garment Workers Union, the power companies, the automobile industries and others.

As previously reported, the seventy-ninth Congress enacted legislation establishing a Federal Employees Health Service which is a further recognition of the importance of industrial medicine. APPENDIX NO 23

COMMITTEE ON SCHOOL HEALTH

This committee met on March 23, 1949, with Drs Morris, Bagnall, McKay, Garland and MacLachlan present Dr Allan R Cunningham, of the Department of Public Health, was a guest.

Whatever is done by the school physician must be done well. This axiom should be the guide in any program designed for the school physician.

Efforts should be continued to interest district medical societies in appointing a committee on school medical services. A section on school health of the Massachusetts Medical Society, as suggested at the Massachusetts Health Conference, might better accomplish this purpose.

The Committee favors the establishment of full-time, trained community health units as recommended by the special commission established in 1947 to study and investigate certain public-health matters (H 1766) and believes that the development of such units with full-time, trained personnel will necessarily assist in the development of satisfactory school health services.

The Committee believes that health education is a basic need

- a By teachers specially trained in this field
- b By guided health experiences
- c By participation such as is provided by school health council and student health councils
- d By attendance of parents at health examinations

The Committee approves in-service training courses for professional personnel for the purpose of improving school medical services

- a To develop effective teacher-nurse conferences for screening and other purposes
- b Basic psychiatric screening methods should be developed in school physicians to enable them to detect cases in need of special expert attention
- c Courses in school health for physicians, should be sponsored by the Massachusetts Medical Society, in collaboration with the Department of Public Health and the schools of public health

APPENDIX NO 24

SUBCOMMITTEE OF THE EXECUTIVE COMMITTEE ON BLUE CROSS-BLUE SHIELD PROBLEMS

The Subcommittee of the Executive Committee on Blue Cross-Blue Shield Problems met at 8 Fenway on Friday, March 25, at 4:00 p m

Your subcommittee was represented at a meeting of the Chairmen of Blue Shield's District Professional Service Committees, Officers of the Massachusetts Medical Society and members of the Blue Shield Board of Directors, held on January 26, 1949, at which the question of charges to limited (over-income) members of Blue Shield was discussed at length. Considerable evidence was presented that fees are not always based on ability to pay. Although it was suggested that charges to limited (over-income) members of Blue Shield be limited to fixed percentages of the basic Blue Shield allowance, this suggestion was discarded, and the Executive Director was instructed to refer cases that could not be resolved in his office to the appropriate Blue Shield District Professional Service Committee. This mechanism is in accordance with the Blue Shield By-Laws as approved by the Council of the Massachusetts Medical Society.

Your subcommittee believes that the unreasonable charges being rendered in certain instances to Blue Shield and non-Blue Shield patients alike are having an adverse effect upon the public-relations efforts of the Massachusetts Medical Society. It is therefore recommended that a subcommittee of the Committee on Public Relations be constituted to investigate the allegation that patients are being charged fees in excess of their ability to pay, and, if such practice exists, to recommend an appropriate remedy.

Because of the severe cut in benefits undertaken on May 1, 1948, Blue Cross now finds itself in the position of being able to liberalize its subscriber contract. To this end it has just completed a series of twenty-one meetings with representatives of subscriber groups throughout the Commonwealth. It is anticipated that in the near future Blue Cross will increase the number of "full-benefit" days from thirty to sixty and the maternity allowance from seven dollars (\$7.00) per day through ten days to a flat seventy dollars (\$70.00) per case.

Your subcommittee has been advised that the formation of a Blue Shield insurance company will in all probability be considered by the American Medical Association House of Delegates in Atlantic City next June. The proposed Blue Shield company would be independent of the Blue Cross company now being organized but would, no doubt, work co-operatively with the Blue Cross company.

Your committee recommends that the Massachusetts Medical Society record itself as favoring the establishment of an independent Blue Shield insurance company to provide Blue Shield coverage for national accounts in areas where coverage is not now available and supplement coverage in areas where existing coverage does not adequately satisfy the reasonable demands of national accounts.

APPENDIX NO 25

COMMITTEE ON BY-LAWS AND COUNCIL RULES

The Committee met at the Harvard Club on March 23, 1949. Present were Drs Edward P Bagg, Albert A Hornor, Elmer S Bagnall, Daniel B Reardon and H Quimby Gallepe.

In order to enhance the efforts of the Director of Medical Information and Education and in order to bring his work before the Council the Committee unanimously recommends the following amendments to the by-laws of the Society as amended May 25, 1948.

1 Chapter IV, Section 1 eliminate the "and" following the second comma in line 4 and insert after the comma following the word "Society" in line 4 the words "The Director of Medical Information and Education."

2 Add to Chapter VI, Section 8, as amended, the following "He shall be a nonvoting member of all committees of the Society, with the exception of the Committee on Ethics and Discipline. He shall be privileged to distribute the information acquired from these committees with the approval of the respective chairmen."

The committee recommends that it be authorized to publish a new volume containing the Digest, By-Laws, Code of

wealth of Massachusetts, it was decided that a study of maternal mortality should be conducted throughout the entire Commonwealth. Through the efforts of Dr. Florence McKay a sum of money was obtained from the Children's Bureau in Washington to finance this study, which will be directed by Dr. Luke Gillespie and Dr. Arthur Edgelow. It has been proposed that a review of maternal deaths be made during the year, and a representative committee will arrive at a decision whether these deaths were preventable or nonpreventable. Plans will be made to review this material periodically at meetings open to the general medical public.

APPENDIX NO. 20

COMMITTEE ON POST-GRADUATE MEDICAL EDUCATION

Attention of the Society is directed to the fact that the work of this committee now includes the New England Post-Graduate Assembly, the directors of various post-graduate exercises carried on throughout the State and the conduct of the Sanders Theater Course.

New England Post-Graduate Assembly

This year the Assembly will meet at the Copley Plaza Hotel on November 9, 10 and 11.

Making full use of past experiences, the organization of various committees from this and other states has been accomplished. By vote of the program committee arrangements have been made to omit the various hospital clinics and in their place to devote a full day to television exercises, both surgical and medical. Other than this note of progress, there is no further report at this time.

Post-Graduate Medical Exercises — Fall and Winter 1948-49

At the outset it should be stated that as a result of a personal survey of the various teaching areas during the summer months, together with certain experiences early in the Fall of 1948, it seemed advisable to all concerned to make certain changes in the teaching framework. As a result, the teaching areas are as follows:

- Area 1 — Pittsfield, North Adams, Great Barrington
- Area 2 — Springfield, Holyoke
- Area 3 — Greenfield, Turners Falls
- Area 4 — Worcester
- Area 5 — Fitchburg, Gardner, Leominster
- Area 6 — Lowell
- Area 7 — Lawrence, Haverhill, Newburyport
- Area 8 — Taunton, Fall River
- Area 9 — Hyannis, New Bedford
- Area 10 — Plymouth
- Area 11 — North Shore
- Area 12 — Greater Boston (Sanders Theater)

The changes indicated above have accomplished a certain amount of decentralization, they have made it possible better to satisfy the desires of local chairmen especially regarding the time of meetings, and finally these changes have made it easier for doctors to get to the meetings. In general, the results have been very gratifying.

In the eleven teaching areas outside Boston, 36 exercises have been conducted under the auspices of this committee. With one or two exceptions, the attendance has been excellent, revealing a definite increase over previous years. However, as in previous years, actual attendance reports are not available. This past year has witnessed the development of a very satisfactory liaison between local chairmen and the Boston group. Undoubtedly this has contributed greatly to the success of the meetings.

Sanders Theater Course

This is the fourth year of these meetings. As usual, under the able leadership of Dr. Hurxthal and the various

program chairmen, an attractive program was arranged. This year it seemed inadvisable to send out registration cards so that we have no figures on total registration. Judged from average attendance, however, the meetings were as well received, if not better, than in previous years.

General Discussion

The aim of postgraduate medical instruction as conducted by the Massachusetts Medical Society is to make available to all physicians in the Commonwealth a certain amount of useful information without charge and with the express purpose of thereby improving medical care. There is no question concerning the interest of physicians in such an endeavor. The real question that constantly confronts your committee is how we can best accomplish the objectives of such an endeavor.

In the light of recent developments in the practice of medicine, it is our belief that this problem merits the attention of all thoughtful physicians. Anything we can do to close the gap that now exists between available medical knowledge in teaching centers and in outlying districts or to stimulate the formation of local teaching centers scattered throughout the State, or both, will help solve the problem of medical manpower distribution and will also help answer some of the current criticisms of medical practice.

Viewed in this larger sense, there is still plenty of work ahead for your committee. It is suggested that we devote more attention to community needs and explore the possibilities of closer affiliation with the Department of Public Health and with the various scientific bodies with headquarters hereabouts. It is also suggested that your committee endeavor to enlist the support of the deans of the medical schools with the thought in mind that it is perhaps not too much to suggest that the medical schools have a certain responsibility in this work.

Of course, a good deal of graduate teaching is going on outside the scope of your committee, and actually some areas have set up teaching courses conducted entirely by local talent. A notable example is the course conducted for the past three years by the Springfield group. Such endeavors should be encouraged, and possibly your committee could help in the formation of study groups in other areas.

These and other considerations are the concern of this committee. We are very conscious of the increasing importance of this work. It is our hope that with the continued co-operation of the members of this Society there will be a constant improvement in the type and scope of postgraduate medical instruction for the betterment of medical practice in this state.

W. R. OHLER, *Chairman*

APPENDIX NO. 21

COMMITTEE ON MEDICAL ECONOMICS

At the request of the Council, the Committee has reviewed the policies of the Society concerning activities that might be questioned by the federal Government in relation to anti-trust laws. Legal counsel assures us that so far as the Blue Shield is concerned the Society and Blue Shield are clear. We are advised that investigation of other activities of the Society is not necessary at this time.

APPENDIX NO. 22

COMMITTEE TO MAKE RECOMMENDATIONS AS TO FUTURE DIRECTORS OF THE BLUE SHIELD

To hold office until 1952

Mr. Eban H. Ellison, Jr., reappointment
Mr. Joseph K. Milliken, Jr., reappointment

revert to the Building Fund. However, the true liquidating value of the Fund must be based on the market value, not book value, of the securities held and in the case of the General Fund, the market value of the securities is \$9183 less than their book value, so actually only \$19,401 can be added to the Building Fund out of surplus this year, and the difference in market and book values held as reserve.

At the beginning of 1948 the total assets of the Building Fund in cash and book value of securities stood at \$76,072. Adding to this the \$19,401 conveyed from the surplus in the General Fund and \$2127 income from the Building Fund securities brings the amount to \$97,600. But loss from sale of securities of \$768 and difference between the market and book values of the securities of \$2154 must be deducted to bring the actual cash value of the Building Fund to \$94,678 at the end of the year.

There is no particular reason to maintain a large General Fund. The amount derived in income from its securities is only 4 per cent of the Society's total income for general expenses, whereas 90 per cent of the income for this purpose comes from assured annual dues. But there is great merit in increasing the Building Fund in every possible way in anticipation of the time permanent headquarters are established and to assure their maintenance without being dependent on income from dues, which should be spent for general expenses covering the activities of the Society.

We enter 1949 with a grand total of assets in cash and securities of \$381,771, an increase of \$24,243 over the previous year.

During the year the following changes have been made in the portfolios. In the General Fund, \$20,000 U. S. Treasury 2½ per cent bonds due 1972/67 were sold, as were 60 shares Consumers Power 4½ preferred stock and 80 shares Monsanto Chemical Company common stock. Purchases in the General Fund included \$10,000 U. S. Treasury 2 per cent bonds due 1954/52, \$10,000 U. S. Treasury 2 per cent bonds due 1951/49, 100 shares Newmont Mining Corporation common stock, 300 shares Wisconsin Electric Power common, 25 shares Allied Chemical and Dye common, 125 shares General Electric common, 70 shares Firemans Fund Insurance and \$6000 Peoples Gas Light and Coke 3 per cent bonds due December, 1963. In the Building Fund were sold 30 shares Consumers Power Company 4½ per cent preferred stock and 50 shares Monsanto Chemical Company common, while purchases were made of 50 shares Newmont Mining Corporation common, 15 shares Abbott Laboratories common, 20 shares Gulf Oil Corporation, common and \$3000 Peoples Gas Light and Coke 3 per cent bonds due 1963.

Because of an added amount of work connected with the Federal Old Age and Unemployment taxation and the State unemployment taxation, retroactive for several years, the Assistant Treasurer made a welcome entry into active participation in the Treasurer's office to handle all tax correspondence. His services have been greatly appreciated, and his status, emerging from that of a figurehead, to one in which he has more intimate contact with the office, should bring with it mutual gratification.

Upon proper authorization the Treasurer wrote a detailed description of the Society's activities to the Treasury Department, Washington, D. C., to ascertain if any operations might be bringing us unwittingly nearer to the brink of liability for federal income taxation as a corporation. The reply was most reassuring, taking up item for item, to affirm that, as now conducted, our endeavors would not endanger our income-tax exemption.

Before it was finally voted to increase the dues to \$25 in 1948, the committee appointed to study the need reported that they advised this amount, somewhat above coverage for the expenses at that time, in order that the dues would not require further increase for many years to come. With this laudable aim in view it is important for the members to consider the narrow margin between the budget of \$142,000 for 1949 and the estimated income of

\$150,000. Whereas it is possible that the whole amount budgeted will not be spent, care should be taken in long-range contemplation to plan to confine the extent of the Society's activities within the limits of the stable income, if it should be deemed advisable that some lines of effort be expanded, others would by necessity have to be curtailed.

APPENDIX NO 26

COMMITTEE ON DIABETES

The Committee has met and considered various means of extending plans for bringing under treatment the undiscovered cases of diabetes of the Commonwealth. The efforts already made by some district societies indicate clearly that the district societies can really carry out diabetes-detection programs most efficiently. The importance of this problem has been recognized by other committees of this society, and it is the desire of the Committee on Diabetes to present with the Committee on Public Health and the Committee on Industrial Medicine the following resolution

WHEREAS, the Massachusetts Medical Society has already approved an attempt to find the undiagnosed diabetic patients of the Commonwealth and bring them under treatment, and

WHEREAS, representatives of a large number of industries in the State have expressed a desire to co-operate with efforts directed at the discovery of latent diabetes in order to secure early treatment,

BE IT RESOLVED that the Council of the Massachusetts Medical Society recommend suitable action by the officers and committees of the district medical societies to carry out appropriate programs aimed at the discovery of diabetes in the community consistent with the Diabetes Detection Program and Diabetes Week sponsored by the American Diabetes Association

APPENDIX NO 27

COMMITTEE ON VETERANS AFFAIRS

A meeting of this committee was held at 8 Fenway on March 9, 1949, to confer with Drs Pratt, Adler and Schultz, of the Veterans Administration, concerning their policies in the outpatient treatment of veterans with neuropsychiatric disabilities

After an extensive study of all neuropsychiatric patients under fee-basis treatment, it has been determined that in general their difficulties are of such complex nature as to require special psychiatric techniques. Unless they receive such specific care, their condition tends to become static, and the final outcome is usually a chronic illness refractory to further measures

In Metropolitan Boston, where specialist resources are readily available, patients are either accepted for treatment at the Mental Hygiene Clinic, Boston Regional Office, or are authorized fee-basis psychotherapy by certified specialists in neuropsychiatry. In exceptional cases or in such areas where specialists' care is not readily available, patients are authorized treatment by the family physician. As required by Veterans Administration regulations, treatment reports are reviewed monthly by a psychiatrist to determine the need for continuation of treatment or necessary changes

On the basis of a number of such reports, it has become obvious that clarification of certain clinical points is in order. The following recommendations are offered as a guide to family physicians treating veterans with neuropsychiatric disabilities

Overemphasis on treatment of functional somatic complaints affords only temporary symptomatic relief while focusing the patient's attention on areas that are actually remote from the real cause of his illness. This has the effect of supporting the patient's reluctance to approach his complaints in emotional terms

Reliance on sedatives or hypnotics to control emotional distress for long periods has led in a number of cases to drug habituation and has thereby created an additional serious problem

Liberal use should be made of either fee-basis psychiatrists or the Mental Hygiene Clinic of the Veterans Administration, Boston Regional Office, for psychiatric consultation, re-evaluation or other specific psychiatric care

Lastly, physicians are reminded that the *Veterans Administration regulations permit the authorization of treatment only for service-connected disabilities*. Patients are not entitled to reimbursement for the treatment of any other illness that may occur concomitantly with their adjudicated service-connected disabilities

The Committee urges that these recommendations be brought to the attention of members of the Society in the *New England Journal of Medicine*. The committee further recommends that all matters of difficulty between the Veterans Administration and the doctors, arising out of the care of veterans, shall be referred to the Board of Review of the Massachusetts Medical Society for their consideration

APPENDIX NO 28

REPORT OF THE TREASURER

With the increase in resident annual dues in 1948 from \$10 to \$25, income from such dues rose from \$59,020 in 1947 to \$134,960. Income from nonresident dues rose from \$2244 to \$2514. Income from censor fees of \$1335, in 1947, fell to \$1053, in 1948. Net profits from the Committee on Arrangements, \$6234 in 1947, fell to \$3153 in 1948, and that from the New England Postgraduate Assembly \$528 in 1947, rose to \$1146 in 1948

Among the endowment funds, the Phillips Fund is the only one with unrestricted use of income, and \$200 was derived from this source in 1948. The incomes from the restricted funds have been applied this year to reduce expenses according to their respective purposes, as will be seen in the detailed expense account—the Brickley Fund toward luncheon expenses of the Committee on Ethics and Discipline, the Shattuck Fund toward the stipend given the Shattuck lecturer, and the Cotting Fund toward the cost of the Cotting luncheons

Income from the securities in the General Fund rose from \$5895 in 1947 to \$6571 in 1948, and in the Building Fund from \$1906 to \$2127. In 1948 there was a loss on sale of securities in the General Fund of \$1026, and in the Building Fund of \$786. This was due to the sale of some of the holdings in Monsanto Chemical Company common stock and Consumers Power Company 4 5 preferred stock in both funds on advice of our investment counselors

The book value of securities held in the General Fund has risen from \$199,150 to \$218,907 and in the Building Fund from \$74,308 to \$75,347. The principal of the Endowment Funds remains at \$28,166

Total revenue in the General Fund was \$149,998 for 1948, and total expense was \$114,640, leaving a surplus of income over expenditures of \$35,358

By previous vote of the Council, the total assets of the General Fund are to be pegged at \$250,000, and any surplus for a given year to be diverted to the Building Fund. At the beginning of 1948 the assets of the General Fund, calculated on cash and book value of securities, was \$243,226, leaving presumably \$6774 to be added to bring the total to \$250,000 and the remainder of the surplus or \$28,584 to

This patient did not have hypertension. Blood dyscrasia was certainly not noticeable in the report.

Let us turn now to the differential diagnosis of the abdominal mass, and then let us see if there is any one diagnosis that will explain both these findings. An abdominal mass that appears to be freely movable, in a patient such as this, may be an ovarian cyst or tumor. I will not go into a classification of ovarian tumors here. A pedunculated fibroid could produce such a mass and so could a cyst of the mesentery, carcinoma of the bowel and, finally, the spleen. Spleens are occasionally on a very long pedicle and may be found anywhere in the abdomen.

Is there any diagnosis that would explain both the post-menopausal bleeding and the presence of a movable mass in the abdomen? Ovarian tumors or cysts that produce estrogen and in turn cause growth of the endometrium and bleeding from it should by definition produce endometrium. I am very much interested in the statement that the uterine curettings were not grossly abnormal. In a woman ten years past the menopause, who has received no estrogen therapy by mouth or parenterally, that statement should mean that there were no uterine curettings, and I should like to ask, if it is a fair question, whether there were curettings at all or whether this statement means that there were curettings but they were not grossly abnormal.

DR MARSHALL K. BARTLETT: There was a moderate amount of tissue that appeared as a result of curettage.

DR ULFELDER: The statement that the uterine curettings were not grossly abnormal means, then, that this did not look like a malignant lesion of the uterine fundus. Were the curettings similar to those ordinarily seen in the pre-menopausal woman?

DR BARTLETT: Essentially the same, I believe.

DR ULFELDER: That very definitely raises the possibility that this patient was making estrogen and therefore growing an endometrium. However, one can get from the post-menopausal uterus material that is reported later by the pathologist as showing atrophic endometrium. If one cures carefully, I am sure it is always possible to get a little something, although occasionally we see nothing at all.

A possible diagnosis therefore in this case is a tumor of the ovary, which made estrogen and caused secondary development of endometrium in this post-menopausal uterus. Such a tumor would be either a granulosa cell or a thecoma or, less likely, a papillary cystadenoma. Carcinoma of the uterus and polyp of the endometrium should have been detected in the curettings, probably grossly. If senile changes had been noted in the vaginal mucous membrane they would have been described in the protocol, particularly since that must have been in the operator's mind as a possible explanation

for the bleeding when he examined this patient. Fibroid could explain the mass but not the bleeding. Fibroids of the uterus do not produce bleeding in the post-menopausal woman.

The only diagnosis I can see that will explain both findings on the basis of one lesion is an estrogen-producing tumor of the ovary, with growth of the endometrium secondary to it. There is one other possible explanation for her bleeding, which I neglected to mention, and that is resumption of normal menstruation. You will note from the protocol that there was some rhythmicity to this woman's bleeding, and that the bleeding was somewhat like periods in that it took place for about five days and then ceased altogether until the next episode. I recall no case in which this has occurred as long as ten years after a cessation of periods on physiologic grounds. I think it is not uncommon for women to have a period or two, as long as eighteen to twenty months after the cessation of periods, but I think that is a most unlikely explanation for the bleeding in this woman after this long interval.

Endocrine-producing tumors of the ovary are rare, and one has to make, therefore, a rare diagnosis, to explain both these findings on the basis of one lesion. It is so rare that I think it is unlikely in this patient. I think it is more likely that these two findings were not associated. I think she had a mass, and I think she had post-menopausal bleeding. I think the post-menopausal bleeding probably will not be explained, and I think the mass was an entirely independent condition. I would consider a spleen as the most likely mass in this patient. The mass was rather high on the left side, and when it was displaced, it was displaced to the right but not down. I am also interested in the statement that the pelvic examination was not remarkable. I think I will "stick my neck out" and say that this patient had a wandering spleen, that she did not have any good explanation for post-menopausal bleeding, and that it is possible, but not likely, that she had an estrogen-producing tumor of the ovary.

DR TRACY B. MALLORY: Is there any further comment? Dr Bartlett, I wonder if you would tell us what you found at operation.

DR BARTLETT: This case was a good example to me of the value of re-examining the abdomen under anesthesia, because this woman had a really sizable mass, — I think "grapefruit size" is a fair description of it, — and yet we had all completely missed it. The mass was easily felt under anesthesia, and it seemed to be symmetrical and smooth. Although when first felt it was in the left side of the abdomen it could very easily be rolled across into the right side, off into the right gutter, so to speak, and then back again. It seemed to lie a little more easily on the left than on the right, and on bimanual examination we were not able to make out any connection with the uterus. We could move the abdominal mass, so far as we could tell, without

CASE 35291

PRESENTATION OF CASE

A fifty-eight-year-old Italian, para IV widow entered the hospital because of vaginal bleeding.

Ten years before admission the patient passed through a relatively uneventful menopause and had no further bleeding until six months before entry, when she suddenly began to spot. This spotting lasted five days and then disappeared completely. She had a similar episode of bleeding two months before admission, which also lasted five days, and then a third episode a month later. There was no associated vaginal discharge or pain and no other symptoms. There was no history of estrogen medication.

Her catamenia had begun at twelve years of age, and her menstrual periods were always regular. She had had a gall-bladder operation fifteen years previously and a second abdominal operation, for some unknown reason, a few years later.

Physical examination showed a markedly obese woman. Examination of the heart and lungs was negative. The abdomen was so obese that no masses could be made out. There was a scar in the right upper quadrant.

The blood pressure was 135 systolic, 85 diastolic. The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a hemoglobin of 13 gm and a white-cell count of 6500, with 63 per cent neutrophils. A vaginal examination was not remarkable.

An operation was performed on the second hospital day. Under anesthesia, a grapefruit-sized abdominal mass was palpated, on the left side above the pelvic brim, but could be pushed across the midline to the right side. The uterine curettings were not grossly abnormal.

A laparotomy was then performed.

DIFFERENTIAL DIAGNOSIS

DR HOWARD ULFELDER The history is that of an obese woman who had her menopause ten years before, who was essentially well in all other respects, who had recurrent episodes of vaginal bloody spotting for six months prior to operation and who, under anesthesia, proved to have a movable mass the size of a grapefruit.

I think it might be useful in this particular case to single out the two outstanding findings and run over the differential diagnosis of each one. The first one, of course, is post-menopausal vaginal bleeding. A common cause for this—in fact, the most common cause nowadays—is exposure to the action of estrogens. We are told that this patient was not given estrogen medication, we must not overlook the fact that she may have been producing her own estrogen. There are ovarian tumors that make estrogen in large quantities. These are the granulosa cell tumor and the thecoma. Certain other ovarian tumors also produce small quantities of estrogen—even papillary cystadenocarcinoma of the ovary occasionally has associated endometrial bleeding without a malignant lesion of the endometrium.

A second cause for post-menopausal vaginal bleeding is a tumor of the uterus. This may be either malignant—carcinoma of the uterine fundus or of the cervix—or benign—a uterine polyp. There are a number of other causes of post-menopausal bleeding. A common one is the senile change frequently noted in the vagina. Senile vaginitis is frequently associated with bloody spotting. It is usually also associated with some degree of vaginal discharge and local irritation. Some people believe that there are senile changes in the endometrium corresponding to this visible change in the vaginal mucous membrane, and it has occasionally been postulated that bleeding from a senile endometrium or endometritis can occur just as we see bleeding from senile vaginitis. This has never been proved. Occasionally, in hypertension, we find post-menopausal vaginal bleeding explained on no other basis. This has been described as uterine apoplexy. It is a concept that is not very strongly held by anyone today but is occasionally mentioned and should be included in the differential diagnosis of this condition.

Blood dyscrasias, of course, can produce bleeding from the uterus as from any other part of the body, and they must be considered. And, finally, there is a group of patients in whom no explanation is ever found for the post-menopausal vaginal bleeding. Unfortunately this is a rather large group. The present state of our knowledge about this symptom is such that there are many patients in whom the most thorough study fails to reveal any cause for post-menopausal bleeding.

Some diagnoses that I have mentioned may be excluded on the basis of the protocol.

of gas was seen in the descending colon and rectum.

The patient was given fluids and blood intravenously and improved somewhat. The hemoglobin, hematocrit and total protein dropped from 17.5 gm per 100 cc, 51 per cent and 7.8 gm respectively, to 15.5 gm per 100 cc, 46 per cent and 6.5 gm. The blood pressure reached a maximum of 110 systolic, 60 diastolic. A urine specimen obtained on the second day gave a ++ test for albumin, and the sediment contained many granular and hyaline casts and 15 to 20 red cells and 10 to 20 white cells per high-power field. The nonprotein nitrogen was 82 mg per 100 cc. The patient's condition never improved enough to warrant operation, and from the middle of the second hospital day, in spite of large amounts of intravenous fluids and blood, she became increasingly comatose, the blood pressure dropped, and the pulse became more rapid and weak. Drainage from a stomach tube at first was dark brown but later became blood stained, and no peristalsis was ever heard. The total urinary output during the patient's hospital stay did not exceed 400 cc. She died early on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR JOHN B. MCKITTRICK: There is only one diagnosis that I can make from the history as recorded, that is, intestinal obstruction, with perforation and peritonitis. Whether one could be more specific than that is problematic, since we have little information beyond the salient features of the short, acute illness. Whether the acute episode was of ten days' or three days' duration is not quite clear in my mind. The history described a "cold and pain in her back, for which she went to bed" ten days before admission. Apparently during the intervening seven days until she began to have lower abdominal crampy pain, and following that vomiting, the course was not remarkable. One does not know whether the back pain persisted and later merged with the lower abdominal cramps, whether there was a subsidence of the back pain and apparent recovery from the cold, or whether symptoms persisted during this period and merged into the more acute and dramatic picture developing three days before admission.

The past history reveals only that twelve years previously a Mikulicz procedure was done for infarction of a segment of sigmoid. It is to be presumed, then, that in the intervening period the patient was free of consequential complaints.

The physical examination and chemical picture on admission to the hospital give us little help beyond confirming the clinical impression of intestinal obstruction. A dehydrated patient in shock, semicomatose, with distended abdomen and evidence of hemoconcentration, is in perfect accord with the picture one sees in late intestinal obstruction. No mention is made of abdominal tenderness, and I think wisely because a patient in this condition

loses the normal response to abdominal palpation. The subsequent course of the blood picture, with return to more normal levels following hydration, electrolyte replacement and transfusion, emphasizes this aspect of the obstruction problem. Such replacement therapy is essential to proper management but must be followed by correction of the underlying disease. In this patient the process was so advanced that operation was not deemed practical.

The elevated nonprotein nitrogen, oliguria and urinary findings of hyaline and granular casts and a few red and white cells do not, I believe, indicate renal disease. Such findings are perfectly consistent with dehydration associated with intestinal obstruction.

Can one, from the information given, reconstruct the course of events and localize the lesion? To go back ten days before admission we find that she complained of what she called a cold and pain in her back. Pain in the back in intestinal obstruction is an interesting symptom, and while not common, when present is very suggestive of strangulation obstruction. However, it is inconceivable to me that this patient had strangulation obstruction for a period of ten days. Therefore I am forced to exclude the symptom of pain in the back from the episode immediately preceding admission. We are then left with a three-day story beginning with lower abdominal crampy pain and, somewhat later vomiting. This suggests that the obstruction was low, rather than high, since the vomiting was a delayed symptom. Vomiting is a much more prominent feature in small-bowel than in large-bowel obstruction. On the other hand, one is more apt to find lower abdominal cramps in large-bowel than in small-bowel obstruction. About 20 per cent of patients, however, will localize pain in small-bowel obstruction below the umbilicus, so that one cannot depend upon the localization of pain entirely. The chemical changes with the rather severe dehydration suggest a marked degree of vomiting within a relatively short period of three days. This is much more suggestive of small-bowel obstruction. It would be unusual, I think, for a patient with the ordinary type of large-bowel obstruction to vomit enough to cause this degree of hemoconcentration and chemical imbalance in this space of time. The x-ray films of the abdomen should help us, and from the description, I would be more inclined to call this large bowel rather than small bowel. Usually, when one has a single loop of small bowel as much dilated as this, the remaining small-bowel pattern is apt to be proportionately distended. On the other hand, one may get tremendous distention of large bowel with relatively little distention of small bowel, or for all practical purposes no distention of small bowel if the ileocecal valve is competent. In a case of an isolated loop of small bowel, however, such as one might find in strangulation

moving the uterus, but one must not forget that this was a very obese patient. This examination under ether gave us the information on which to decide to do a laparotomy, and when that was done it was apparent that the mass was a cyst arising in the left ovary on a long, stretched-out pedicle. It was of the size described and was smooth on the outside, with a moderately thick wall but with no external projections on it. The tubes and the other ovary were not unusual. The uterus was somewhat larger than one would expect after the menopause but again was not definitely beyond normal limits. A total hysterectomy was carried out, both tubes and ovaries being removed.

CLINICAL DIAGNOSIS

Ovarian cyst

DR ULFELDER'S DIAGNOSES

Post-menopausal uterine bleeding of unknown etiology
Wandering spleen
Second choice: estrogen-producing tumor of ovary

ANATOMICAL DIAGNOSIS

Granulosa cell tumor of ovary

PATHOLOGICAL DISCUSSION

DR MALLORY: The specimen Dr Bartlett removed was a soft, fluctuant tumor mass, which looked and felt like a cyst. On cutting across it, we found that there were cystic areas and also solid tumor foci. One of the cystic areas contained some almost cheesy material. There were also shaggy, papillary masses projecting into the cyst. From the gross examination we thought that it was probably a papillary cystadenoma of the ovary, and were considerably surprised when the microscopical sections came through to find that the solid portions of the tumor showed a very characteristic, unmistakable pattern of granulosa cell tumor. The endometrium was not obviously hyperplastic. There was slight cystic dilatation of some of the glands, but the epithelium was fairly tall, and was not of the atrophic type seen in the senile cystic endometrium. There was a very mild hyperplasia present.

Are there any questions that anyone would care to ask?

DR ALFRED KRANES: I still do not understand why Dr Ulfelder started what sounded like a perfectly logical diagnosis, but because of its rarity, made a rarer diagnosis.

DR ULFELDER: In my experience a wandering spleen is less rare than granulosa cell tumor.

DR KRANES: Really?

DR MALLORY: I will certainly back up Dr Ulfelder in his statement that when uterine cancer is excluded we are unable to find any pathological reason for post-menopausal bleeding in the majority

of cases when we are supplied with the ovaries and uterus.

DR BARTLETT: Dr Mallory, would this endometrium be unusual, in a case of unexplained post-menopausal bleeding?

DR MALLORY: I do not believe there was enough change in it so that I would have probably picked it up, if I had been given the curettings alone. I do not believe I would have made a diagnosis of hyperplasia, and I would not have suspected at all strongly granulosa cell tumor. Sometimes, when there is frank hyperplasia, we have been able to suggest the diagnosis on the basis of curettage.

CASE 35292

PRESENTATION OF CASE

A forty-nine-year-old housewife entered the hospital because of abdominal pain and vomiting.

Ten days before admission she had a cold and pain in her back, for which she went to bed. Three days before admission she noted the onset of lower abdominal crampy pain and somewhat later vomiting. She failed to pass anything by rectum except under the stimulus of enemas, when on two separate occasions small amounts of gas and hard feces were obtained. The vomiting continued and became brown in color. On the day of admission she became cold and clammy, and the pain diminished.

Twelve years before admission a Mikulicz procedure had been performed, with resection of an infarcted segment of sigmoid. One month later a laparotomy was performed, and obstructed loops of small bowel were freed from around the sigmoidostomy. One year later the sigmoidostomy was closed.

Physical examination revealed a semicomatose, very pale, clammy, cold woman in no acute pain. The lips were dry, the chest was clear, and the abdomen was distended and doughy with a nontender hernia (3 cm in diameter) in the left upper rectus scar. The skin over the hernia showed a slight, bluish discoloration and was hot to the touch. No organs or masses were palpable, and no peristalsis was audible. Pelvic examination showed a lacerated, freely movable cervix, no masses or tenderness was made out. Rectal examination was likewise negative for masses and tenderness, the rectum was empty.

The temperature was 103.2°F, the pulse 100 and the respirations 25. The blood pressure was unobtainable.

Examination of the blood revealed a red-cell count of 5,000,000, with a hemoglobin of 16 gm, and a white-cell count of 16,000. An x-ray film of the chest was normal. A plain film of the abdomen showed a loop of bowel measuring 12 cm lying across the right midabdomen, and numerous moderately dilated loops of small bowel. A small amount

CORNERSTONE OF THE TEMPLE

ISRAEL'S Hebrew University-Hadassah Medical School, in accordance with an announcement previously published, was inaugurated on May 17 in a joint international ceremony taking place simultaneously in Jerusalem and at the Israeli Consulate in New York. Participating in the creation of the first school of medicine in the new state were Dr Chaim Weizmann, president of Israel, and American medical scientists, teachers and administrators

A symbolic part of the ceremony was the presentation by Warren R. Austin, United States ambassador to the United Nations, of a block of Vermont marble. This stone, a product of the same quarry that is supplying material for the United Nations permanent headquarters, was ac-

cepted by Mrs Haim Yassky, of Jerusalem, widow of the late Hadassah medical director. It will become 'cornerstone of the cornerstone' of the new medical-school building soon to be erected on Mt Scopus, near Jerusalem

From the days of ancient Israel and the lessons in hygiene that came from Judea, Jewish medicine has traced its brilliant course. As Dr Weizmann said, the school will be another "vehicle in the struggle to make the ideals of social progress and democracy realities, not only in Israel but throughout the Middle East"

It is another aspect of America's program to make the benefits of scientific advances available to other governments and other peoples. It is another instance of American generosity, and a manifestation of American Jewry's profound awareness of the meaning of Jewish history and tradition and their sensitivity to the cultural and physical needs of Israel today

May the building of this university on a hill in Palestine be another step in the bringing of peace to a troubled land, and to a scattered race a home that it may look to, even if only a few inhabit it!

"BY THEIR FRUITS"

AFTER the death in September, 1947, of Dr Robert Nason Nye, late editor of *The New England Journal of Medicine*, certain sums of money donated by his friends to the American Cancer Society were set aside for a definite purpose. This particular purpose, as announced in the editorial columns of the *Journal* on February 26, 1948, was an evaluation of the effects of radiation on the personnel of x-ray departments

Approximately \$2500 had been donated, which was later augmented by another \$1000 from an anonymous giver, and this sum was voted as a grant to the Massachusetts General Hospital for the study in question. Already this study has borne first fruits, which are incorporated in the report by Hunter, Merrill, Trump and Robbins, appearing as the leading article in the present issue of the *Journal*

The technical terms in which much of this preliminary report is necessarily written suggest certain more easily comprehended conclusions. Scattered diagnostic radiation, formerly thought to be soft and

obstruction, it would be very easy to have an x-ray picture not dissimilar to that described. The small amount of gas seen in the descending colon and rectum may have passed the point of obstruction or may have been introduced at the time of the numerous enemas, so I think we must exclude this as a significant finding, particularly in view of the patient's condition.

It seems to me that the most logical explanation for this picture is an isolated loop of small bowel with strangulation of the mesentery causing infarction with subsequent perforation and peritonitis. I cannot fit the whole picture logically with the diagnosis of large-bowel obstruction. I say this because of the short history, the amount of vomiting, the degree of dehydration and the rapidity of the downhill course, all of which are much more consistent with obstruction of the small as opposed to the large bowel. The blueness described in the area of the hernia may well have represented the bloody fluid associated with strangulation obstruction, or could simply have been the peripheral collapse and local congestion associated with peritonitis. However, I would not be a bit surprised to find that the patient had purulent, bloody fluid within the abdominal cavity.

My diagnosis, then, is small-intestine obstruction, mechanical in nature, with strangulation, perforation and peritonitis. I can only guess at the mechanism. A loop of bowel could have been caught in the hernia, even though the hernia was soft, or an intra-abdominal band may have precipitated the difficulty.

CLINICAL DIAGNOSES

Strangulation obstruction of small bowel due to adhesions and volvulus
Peritonitis
Cerebral thrombosis

DR. MCKITTRICK'S DIAGNOSIS

Intestinal obstruction, mechanical, with strangulation, perforation and peritonitis

ANATOMICAL DIAGNOSES

Thrombosis of portal vein and branches of superior mesenteric vein

Infarction of segments and of small bowel

PATHOLOGICAL DISCUSSION

DR. AUSTIN L. VICKERY: The peritoneal cavity contained 700 cc of hemorrhagic fluid. Loops of both small and large bowel were distended, but although there were numerous old fibrous adhesions binding loops of jejunum and sigmoid to the old abdominal scars, there was no evidence of kinking of the bowel or signs of mechanical obstruction. Three segments of small bowel extending from mid jejunum to midileum were dark, reddish black and contained masses of blood in their lumens. The intestinal wall in these sites was edematous, friable and markedly hemorrhagic, with the intervening segments of small intestine presenting a bluish discoloration but lacking the picture of frank infarction of the previously mentioned loops. The mesenteric veins draining the infarcted sites of jejunum and ileum contained thrombi, which on microscopical examination proved to show signs of early organization. The portal vein showed a similar thrombotic process.

In the absence of an intra-abdominal inflammatory lesion, neoplasm or evidence of mechanical bowel obstruction, it appears that this case would fall into the category of idiopathic mesenteric venous thrombosis. In such cases the thrombi are bland in nature without evidence of inflammatory reaction in the wall of the vein or in the perivascular zones, and the etiology is obscure or conjectural. It is possible that a partial volvulus with torsion of the mesentery initiated the thrombotic process and that the resultant distention of involved intestinal loops effected a spontaneous reduction in the mechanical deformity.

"BY THEIR FRUITS"

AFTER the death in September, 1947, of Dr Robert Nason Nye, late editor of *The New England Journal of Medicine*, certain sums of money donated by his friends to the American Cancer Society were set aside for a definite purpose. This particular purpose, as announced in the editorial columns of the *Journal* on February 26, 1948, was an evaluation of the effects of radiation on the personnel of x-ray departments.

Approximately \$2500 had been donated, which was later augmented by another \$1000 from an anonymous giver, and this sum was voted as a grant to the Massachusetts General Hospital for the study in question. Already this study has borne first fruits, which are incorporated in the report by Hunter, Merrill, Trump and Robbins, appearing as the leading article in the present issue of the *Journal*.

The technical terms in which much of this preliminary report is necessarily written suggest certain more easily comprehended conclusions. Scattered diagnostic radiation, formerly thought to be soft and

comparatively harmless, is now shown to be relatively hard and penetrating. Consequently the roentgenologist must plan the protection of himself and his associates, so far as possible, from these marrow-reaching rays. The danger to the chance observer or to the patient is negligible. It is the daily exposure, month after month and year after year, from which the worker must be guarded.

Fortunately protection against scattered radiation is simple to attain by the means that are suggested, and the advice is offered that manufacturers of equipment could themselves provide more adequate protection for the examiner than is at present afforded.

DISTINGUISHED ALUMNUS

HARVARD University has again hewn to the line in its recognition of academic merit by the

whom twenty-five generations of medical students have held in affectionate regard, thus becomes the first Negro to hold a professorship in Harvard University.

Dr. Hinton, who was born in Chicago in 1883, graduated from Harvard College in 1905 and from Harvard Medical School in 1912, and then served as a voluntary assistant in the Pathological Laboratory of the Massachusetts General Hospital until 1915. He joined the staff of the Harvard Medical School in 1923 and has remained on it consistently ever since, his most recent appointment prior to his present professorship having been that of lecturer on bacteriology and immunology. He has been a fellow of the Massachusetts Medical Society since 1913.

In addition Dr. Hinton has been director of the Laboratory Department of the Boston Dispensary and chief of the Wassermann Laboratory of the Massachusetts Department of Public Health since 1915, and for the past thirteen years chief of the laboratories of the Boston Floating Hospital. He is a special consultant to the United States Public Health Service, consultant to the Massachusetts School for Crippled Children, and a lecturer at Simmons College.

Dr. Hinton, also an authority on rabies, is best known for his research in syphilology and for the development of the Hinton and the Davies-Hinton tests for syphilis.

Certain lines that were written in commemoration of the University's two-hundredth anniversary, a hundred and thirteen years ago, seem to reaffirm a still unaltered code:

*With freedom to think and with patience to bear,
And for right ever bravely to live*

WILLIAM A. HINTON, S.B., M.D.

appointment of Dr. William A. Hinton as clinical professor of bacteriology and immunology in the Harvard Medical School. Dr. Hinton, the friend

The Dental Recorder of July 1st, gives an account of curing tooth-ache by steam, on the Ohio River. The fellow who performed, had rights to sell, and of course belonged either to Connecticut or Massachusetts. People are injuring themselves exceedingly by drinking soda immoderately, this warm weather. They should abstain, too, from gormandizing on ice creams late in the evening.

MASSACHUSETTS MEDICAL SOCIETY

OPPORTUNITIES FOR PHYSICIANS

West Pembroke, Maine, offers a good opportunity for a general practitioner. There is no other doctor in the town than the retiring incumbent, Dr C E Chapman. The nearest hospital is in Eastport, twelve miles away. Any interested physician should make contact with Dr Chapman.

The Western Maine Sanatorium, West Minot, Maine, is in need of a physician. Application for further information should be made to Dr Lester Adams, superintendent.

DEATHS

DONOVAN — Arthur B. Donovan, M.D., of Brookline, died on June 22. He was in his fifty-second year.

Dr Donovan received his degree from Tufts College Medical School in 1923. He was a former member of the staffs of Mt. Auburn, St. Margaret's, Boston Living-in, Boston City, Harley and Whidden Memorial hospitals, and for the last five years had been chief surgeon of the Lumberman's Mutual Casualty Company. He was a member of the Boston Gastro-Enterological Society.

His widow, three sons and a daughter survive.

PERKINS — Franklin A. Perkins, M.D., of Dorchester, died on June 5. He was in his sixty-sixth year.

Dr Perkins received his degree from College of Physicians and Surgeons, Boston, in 1911.

His widow and a sister survive.

ROCKWELL — Alfred E. P. Rockwell, M.D., of Shrewsbury, died on June 19. He was in his eightieth year.

Dr Rockwell received his degree from Boston University School of Medicine in 1899. He was a fellow of the American Medical Association.

His widow and a brother survive.

ROSENBLUM — Carl W. Rosenbloom, of Holioke, died on March 2. He was in his sixty-third year.

Dr Rosenbloom received his degree from Tufts College Medical School in 1909.

His widow, a son, a daughter and three sisters survive.

TAURO — Emily C. Tauro, M.D., of Stoneham, died on June 23. She was in her forty-eighth year.

Dr Tauro received her degree from Boston University School of Medicine in 1927.

Her husband and a daughter survive.

MISCELLANY

UNIVERSITY OF VERMONT

A cardiovascular unit has been established at the Bishop DeGoesbriand Hospital by the College of Medicine of the University of Vermont for the special study and care of cardiovascular patients by means of modern scientific methods. It went into operation on July 1.

Investigative work, now in progress, is partly supported by funds from the National Heart Institute and the American Heart Association.

The staff of the unit is composed of W. Raab, M.D., F.A.C.P., Director, E. Lepeschkin, M.D., J. H. Bland, M.D., and R. J. Humphreys, M.D.

A cardiovascular outpatient clinic, conducted by C. M. Terrien, M.D., will function in close co-operation with the unit.

One of the first activities of the new unit was a refresher course in cardiovascular disease for practicing physicians, given in June. Guest speakers were Dr. Paul D. White, of Boston and Dr. Mercier Fauteux, of Montreal.

INTERNSHIPS IN VETERANS
ADMINISTRATION HOSPITALS

The Veterans Administration is offering 259 internships to qualified graduates of recognized medical schools in three hospitals beginning July 1, 1950. Pilot programs have already begun in two of these hospitals, at McKinney, Texas, and Chamblee, Georgia, affiliated, respectively, with Southern Medical College and Emory University.

The intern program will be conducted under the direction of the deans' committees and in co-operation with medical schools in the vicinity of the hospitals selected. Medical, surgical and rotating services are being offered.

AMERICAN NEUROLOGICAL ASSOCIATION

At the seventy-fourth annual meeting of the American Neurological Association, held in Atlantic City, New Jersey, from June 13 to 15, the following officers were elected for the year 1949-1950: president, Dr. Henry W. Woltman, first vice-president, Dr. Johannes M. Nielsen, second vice-president, Dr. E. Jefferson Browder, secretary-treasurer, Dr. H. Houston Merritt, and assistant secretary, Dr. Charles Rupp.

CORRESPONDENCE

HEPATITIS WITHOUT JAUNDICE

To the Editor: Dr. T. J. Domenici, in the January 20 issue of the *Journal*, reported the cases of 4 patients and stated that they had hepatitis without jaundice or hepatomegaly. That such a syndrome exists is not denied by any physician, but I should like to point out certain facts. If these patients had infectious hepatitis, the group formed a minor epidemic of the disease. It is curious that none of them or their associate nurses are said to have had jaundice, clinically or chemically.

A transient elevation in the cephalin-cholesterol flocculation and thymol turbidity tests is not, in itself, evidence of parenchymal liver damage. These laboratory phenomena indicate only that there is some nonspecific change in the serum proteins.

A more sensitive test of liver function — the bromsulphalein reaction — should be abnormal before it should be concluded that these patients had liver disease.

Visualization of the size of the liver by a scout film of the abdomen would have helped.

Of particular interest was the fact that the third patient had a diarrhea, consisting of four or five watery stools a day. In contrast to the battery of blood studies that she received, examination of her feces might certainly have been done.

It is not impossible that these patients had *amebic* hepatitis, or *amebiasis* without hepatitis, it seems to me.

I believe that the author is only entitled to assert, on the basis of his clinical reports, that he saw 4 young women with indeterminate gastrointestinal complaints and weight loss, who exhibited right-upper-quadrant tenderness and changes in certain laboratory tests that are usually considered evidence of liver damage. The evidence for infectious hepatitis is wanting.

Brooklyn, New York

JOHN W. WALSH, M.D.

Dr. Walsh's letter was referred to Dr. Domenici, who replied as follows:

To the Editor: The absence of jaundice, both chemically and clinically, in hepatitis cannot be considered unusual, since it was not uncommon in soldiers in World War II. Barker, Capps and Allen, in their article "Acute Hepatitis in the Mediterranean theater, including Acute Hepatitis without Jaundice" (*JAMA* 128:997-1003, 1945), state

that "hepatitis without jaundice was probably as common as hepatitis with jaundice in the Mediterranean theater"

The elevation of the cephalin-cholesterol flocculation and thymol turbidity was more than transient. The cephalin-cholesterol flocculation actually followed the clinical course rather closely. It is well known that these phenomena result from a change in serum protein. In some cases, this change is secondary to parenchymatous liver damage. Yardumian and Weisband, in their article "Cephalin-Cholesterol Flocculation Test in Liver Disease" (*Am J Clin Path* 13 383-392, 1943), state that "when there is parenchymatous liver damage the cephalin-cholesterol flocculation test is invariably positive." In their series of cases, all cases with liver disease gave a positive result, 90 per cent of unselected controls were negative. Rosenberg and Soskin, in their article "Comparison of Cephalin-Cholesterol Flocculation Test with Various Criteria of Liver Function (with note on significance of hyperexcretion of hippuric acid)" (*Am J Digest Dis* 8 421-432, 1941), found "the cephalin-cholesterol flocculation test to be positive in 98 out of 100 cases of 'unquestionable' liver disease." In the same series of cases the bromsulphalein test was positive in only 68 per cent. It is the belief of the authors that the cephalin-cholesterol flocculation is the most sensitive test available.

As already indicated, it is not a unanimous opinion that the bromsulphalein reaction is the most sensitive test of liver function. As a matter of fact, some consider it one of the least sensitive tests. Moreover, it is accepted teaching that in determining liver damage, it is necessary to use a battery of tests since any one procedure may not be informative and actually misleading.

X-ray study was performed in all these patients, and no mention was made of liver shadow, although, admittedly, it was not looked for specifically.

Only 1 patient had diarrhea. This, however, does not excuse the lack of stool examination for ova and parasites. Amebic hepatitis or amebiasis without hepatitis, however, must certainly be an outside possibility in nurses who have not been out of New England or in the armed forces.

It is true that the gastrointestinal complaints were vague, but anorexia and sharply localized tenderness in the upper right quadrant were definite.

"TO LIMP"

To the Editor: In the review of *Peripheral Vascular Diseases: Diagnosis and treatment*, by David W. Kramer, M D, published in the *Journal* for June 30, the reviewer, obviously a competent person, makes the common mistake of interpreting the term "claudication" as "cramps." It is a small point, perhaps, but claudication comes from the verb "to limp," not "to close." It therefore means correctly "limp." When put as a question, incidentally, the correct answer has never been given me by student, house staff or visiting physician.

It is interesting that neither author nor reviewer has checked the correct definition of the word. Originally the description was an objective one, and not a subjective one of "cramps."

ALBERT S. MURPHY, M D
Boston, Massachusetts

Note: Neither Webster nor Dorland gives any other definition for claudication than limping or lameness, as indicated by Dr. Murphy.—Ed

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Occupational Marks and Other Physical Signs: A guide to personal identification. By Francesco Ronchese, M D, instructor in dermatology, Boston University School of Medicine, and dermatologist-in-chief, Rhode Island Hospital,

Providence, Rhode Island. With a foreword by John G. Downing, M D, professor of dermatology, Boston University School of Medicine and Tufts College Medical School. 8¹/₂ cloth, 181 pp., with 151 illustrations. New York: Grune and Stratton, 1948. \$5.50.

In this essay Dr. Ronchese discusses the dermal marks, including calluses and scars, met with in various occupations. Some space is devoted to the mouth, nails and hair. There is a special chapter on the legal aspects of deceptive markings. Two fifths of the volume is text, the remainder is devoted to the instructive illustrations. There is a large bibliography and a good index. The book is well published, and the illustrations are excellent. One is reminded of Dr. A. Conan Doyle and his famous character of Sherlock Holmes and his knowledge of physical markings that he used in his profession. This book should be in all collections on dermatology and medicolegal medicine.

Physician's Handbook. By John Warkentin, Ph D, M D, and Jack D. Lange, M S, M D. Fifth edition. 16¹/₂ cloth, 294 pp., illustrated. Palo Alto, California: University Medical Publishers, 1948. \$2.00.

This fifth edition of a popular pocket handbook has been fully revised and brought up to date. It presents a summary of diagnostic and clinical procedures and of facts, readily available for quick reference by general practitioners on their visits. Important tables are printed on the paper covers—a practice not to be encouraged. There is a good index. The binding is of the ring type.

ANNOUNCEMENTS

Dr. Constance Curtiss announces the opening of an office at 21 Bay State Road, Boston, for the practice of internal medicine.

Dr. Earl S. Seale announces the removal of his office to 99 Bay State Road, Boston.

NEW ENGLAND PEDIATRIC SOCIETY

A meeting of the New England Pediatric Society will be held on Wednesday, September 28, in Boston. The afternoon clinical session will be conducted by Dr. Allan Butler and his staff in the amphitheater of Building C, Harvard Medical School. The evening meeting will be held at Longwood Towers.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC.

New bulletins, incorporating changes made at the recent meeting of the Board, are now available for distribution upon application and give details of all new regulations.

The next scheduled examination (Part I), written examination and review of case histories for all candidates will be held in various cities of the United States and Canada on Friday, February 3, 1950. Application may be made until November 5, 1949. Application forms and bulletins are sent upon request to the American Board of Obstetrics and Gynecology, 1015 Highland Building, Pittsburgh 6, Pennsylvania.

WARREN TRIENNIAL PRIZE

The Warren Triennial Prize for the best dissertation on some special subject in physiology, surgery or pathology will be awarded this year. Essays may be written in English, French or German and must be typewritten and suitably bound. Work that has previously been published will not be considered, and original work will be given a high value. Essays will be received until November 15, 1949. The awards will consist of a first prize of \$1500 and a second prize of \$500.

The judges will be the General Executive Committee of the Massachusetts General Hospital.

FRACTURES OF THE TIBIAL SPINES*

CHARLES H. BRADFORD, M.D.,† RONALD W. ADAMS, M.D.‡ AND H. KELVIN MAGILL, M.D.§

BOSTON

FRACTURES of the tibial spines, like all the less common fractures, receive so little attention in medical literature that even the specialists lose contact with the trends of treatment. It seems justified, therefore, to give this topic a thorough airing on the principle of "let sleeping dogs wake," even though our discussion may fail to contribute any vitally new ideas. The occurrence, recently, of 5 cases in our combined observation gives practical significance to such a review.

In this age of radiology it is apt to be forgotten that the entire foundation of knowledge of fracture pathology was established, before roentgenography, by keen observers in the nineteenth century who reconstructed the mechanics of the injury from their findings at autopsy. A search of the literature reveals that descriptions of tibial-spine fractures originated in just such a manner. According to Roth,¹ the first report came from Paris, the source of so much medical knowledge. There, in 1875, Poncet² described the case of a victim who had fallen three stories to his death. Examination of his knee showed "a tearing off of the spine of the tibia by the anterior crucial ligament, all the portion of bone that constitutes this eminence was torn off." In the place of the spine of the tibia, there was a hole that looked as if it had been made with a punch. Within a year, confirmation of a similar finding came from Germany. This patient received an injury to his knee when he was thrown out of a public house. The resulting hemarthrosis became infected, and amputation was performed, ending in the patient's death. On dissecting the knee joint, Dittel³ discovered that "the anterior crucial ligament was detached at its lower end, having torn with it an oval piece of the upper surface of the tibia."

These two simple descriptions contain almost all that need be known about the bone defect in this type of case. It is significant to note that this fracture is an avulsion, not so much of the *spine* of

the tibia, to which the anterior crucial ligament does not actually attach, as of the osteochondral fragment just anterior to the spine, where the cruciate ligament does insert. More properly then, these are "crucial-ligament fractures," as Lange⁴ calls them. They occur most commonly in the young or adolescent, and thus are counterparts of crucial-ligament tears in older age groups. The bony fragment may be torn off completely. More commonly

FIGURE 1 Mechanism of Fracture

it is only slightly displaced at its posterior margin beneath the spine of the tibia, whereas in the anterior portion it is elevated upward and backward as though it had stopped in the middle of a somersault (Fig. 1).

MECHANICS OF FRACTURE

The mechanism producing this displacement can easily be explained if one recalls that the anterior crucial ligament fastens the tibia to the femur much as a set of handcuffs fastens together the constable and his prisoner. It resists backward displacement of the femur on the tibia, or vice versa, and it also

(Notices concluded on page xiii)

the knee. Since the cruciate ligament resists excessive motion of this type, it is natural that an undue strain in the rotational direction should cause the fracture. Pringle, as cited by Jones and Smith⁶ emphasized the importance of this mechanism and was able to demonstrate it experimentally on a specimen. We believe this to have been the mechanism in a case reported below (Case 4).

a typical case of this sort, in which the upper fragment of an old fractured spine had become embedded against the inner surface of the lateral condyle of the femur.

DIAGNOSIS

The diagnosis of fracture of an anterior cruciate ligament is suggested by a characteristic history

C

D

FIGURE 2 Roentgerograms of A. C.

Knees after reduction by manipulation, showing replacement of the anterior cruciate ligament.

Still a third fracture mechanism has been described by Jones and Smith⁶ and quoted by numerous authors. It occurs relatively seldom and has not appeared in Clarke's⁹ series nor in our own. In these cases, the lateral spine of the tibia may be fractured without avulsion if the lateral femoral condyle smashes medially against it. Such an event is more apt to occur in association with fractures of the tibial condyles, or when the collateral ligament is stretched or torn. It can only take place when the lateral tibial spine is longer or sharper than usual, and Jones and Smith⁶ showed that there is a wide disparity of skeletal development in this respect. In dissection, Jones was able to demonstrate

of injury followed by swelling and hemarthrosis, with pain in the knee joint and inability to extend the knee. In the acute stage it is doubtful if this type of locking can be distinguished from that of a torn cartilage, though Jones describes a difference in the feeling of bony resistance.

Certainly, this sign cannot be relied upon completely, and in one of our cases the similarity was great enough to deceive us as described below. The outstanding clinical picture is that of "internal derangement," and the surgeon who sticks to this diagnosis will find it the most discreet as well as the most euphonious pronouncement he can make in the early stages. Roentgenography will, of course,

checks excessive inward rotation of the tibia on the femur. If the body weight is thrown backward at a time when the knee is bent, with the tibia pressing forward, the full force will be exerted against the attachment of the anterior cruciate ligament, and it is here that the lock of the handcuffs will break open if fracture occurs. As it does so, the soft bony fragment to which it is attached jerks

He reproduced all these injuries by forcing the tibia violently forward in relation to the femur, or by reversing the blows, and forcing the femur backward in relation to the tibia. He cited a most interesting case reported by Ross,⁶ in which these mechanical forces had accidentally been given a clinical demonstration. This occurred when a heavy block, which was secured under tension by a cable, tore

A

B

FIGURE 2 Roentgenograms of N. C.

Views before and after reduction by manipulation, showing upward displacement of the anterior cruciate insertion

upward, leaving a punched-out depression in the superior surface of the tibial articulation.

A particularly interesting study of the pathomechanics of this fracture was presented in 1922 by Blaisdell⁵ in connection with experiments performed on cadavers. He worked out what he called the "crucial triad," representing the three types of injury that might follow undue strain on the anterior cruciate ligament. The first was avulsion of the osteochondral fragment at its insertion, as already described, the second, rupture of the cruciate ligament itself, and the third, avulsion of the attachment of the ligament from its point of origin on the inner side of the lateral femoral condyle

loose and catapulted against the back of a man's calf, just below the knee. By good luck, the man was wearing high rubber boots, rolled down at the knee, which had the effect of dispersing the force and which protected the skin from compounding Callender's⁷ old, and not always reliable, rule that "bone gives way before fibrous tissue" was borne out in this case, for the final injury sustained was an avulsion fracture of the anterior cruciate attachment.

In addition to the back-and-forth strain, it must be remembered that avulsion fractures of the anterior cruciate ligament may be caused by inward rotation of the tibia, producing a simple twist of

to the side of the tibial tubercle. The bit emerges in the floor of the cavity from which the bony fragment was avulsed. A second hole is drilled parallel to the first and No. 2 chromic catgut is then threaded up through one hole, matted through the fragment and brought down through the other hole to be tied over the tibial bridge (Fig. 3). Any alternative method of fixation would probably be equally effective, and Roth¹ has even stated that no fixation is necessary, once the fragment has been reduced and the leg secured in extension. Certainly greater security can be felt after the joint is opened if the surgeon has anchored down his reduction with some form of fixation. A stovepipe plaster is then advisable for not less than three weeks, after which gradual knee motion should be resumed actively.

CASE REPORTS

CASE 1* E. B., a 22-year-old woman could give no details of her accident except that she fell off her bicycle and in doing so felt a sudden pain in the right knee. She was treated at first for a sprain, but x-ray examination showed the fracture, consisting of a mild upward displacement of the anterior cruciate attachment with its osteochondral fragment. No reduction was necessary. A stove-pipe cast was applied for 4 weeks, and walking was allowed. The patient made a full recovery and when seen again at the end of 7 months had resumed full, normal activity, with no complaints whatever.

CASE 2. N. C., a 15-year-old boy, was thrown from his bicycle and was brought to the hospital with his left knee in about 15° flexion. He was unable to extend it or to bear weight. He could flex the knee to 90°. An attempt to test the cruciate ligaments proved so painful that it was not carried out in full. X-ray films revealed elevation of the anterior spine of the tibia, together with a moderately large fragment from the upper tibial epiphysis. An attempt was made to reduce this fracture under anesthesia. Full extension could not be obtained until the operator placed his right and left thumbs on either side of the patellar tendon and pressed in deeply as he manipulated the knee toward extension. A sudden snap was then felt, giving the impression that this misplaced fragment had been reduced. Full extension could then be easily obtained, and in this position a long leg cast was applied. The patient's postoperative course was uneventful. He was allowed on crutches on the 4th hospital day and was discharged on the 10th day, to be followed in the Out-Patient Department. The cast was retained for 3 weeks, after which he was allowed to walk on crutches without weight bearing. On his last visit, at the end of 3 months, he showed full, normal range of motion, and stated that he had no disability whatever. He was not limited in any way in his activity, and he had no pain.

CASE 3. C. W., a 29-year-old man, fell about 20 feet from a ladder and landed on his feet. At first he did not realize that he had been injured, but after 30 minutes there was a dull pain in the right knee, and he was unable to extend it fully. After 8 days, he came to the hospital. Flexion to 90° was readily obtained, but extension beyond 165° could not be carried out without severe pain. The patient localized his pain in the anterior compartment just behind the patellar tendon. X-ray films were regarded as normal though subsequent examination revealed the fracture with very slight displacement on the lateral view and none on the anteroposterior view. The patient was operated on under the diagnosis of probable torn cartilage. The anterior cruciate ligament with the tibial spine and a portion of the adjacent tibial plateau were found avulsed in a roughly quadrangular manner, and displaced upward into the anterior compartment of the knee. A tunnel suture was carried out by the technique described above. A plaster cast was applied, and postoperatively x-ray films showed the fragment in good position,

with normal joint space. The patient proved particularly unco-operative, and in spite of all efforts, he persisted in keeping the knee rigid after the cast was removed at the end of 4 weeks. This continued for 3 months, and resulted in an almost completely stiff knee. Manipulation under anesthesia at the end of this time succeeded in flexing the knee to 90° without difficulty, but it is estimated that another 3 months will be required before normal motion is regained.

CASE 4. A. M., a 46-year-old man was injured while shoveling dirt from the bottom of an 8-foot trench when the ground caved in and buried him up to the level of his knees. While he was thus immobilized, a chunk of tarred surface, about 75 pounds in weight, skidded against his thigh so hard that he was thrown in a semicircle to the left and backward while his legs were still firmly planted in the gravel. After being freed, the patient was unable to walk, and his knee was swollen. X-ray examination revealed a fracture of the anterior tibial spine of the left knee. The knee could be fully extended without anesthesia, and a plaster cylinder was applied in this position. Quadriceps-setting exercises were permitted while the leg was in plaster. The cast was removed after 1 month. At the end of 12 weeks the patient walked with a slight limp. He still lacked 5° of full extension. Flexion was normal. After 16 weeks, there was no loss of extension or flexion, but some degree of quadriceps atrophy was still present.

CASE 5. P. A., a 14-year-old girl, was knocked off the bicycle that she was riding, and when her right foot struck the ground there was immediate pain in her right knee. In the course of the next few hours, the knee became markedly swollen, and she was unable to extend it. She was given a general anesthetic, and her physician manipulated the knee so that extension was obtained. After consultation an x-ray examination disclosed an avulsion fracture of the tibial spine, and the knee was then immobilized in a plaster cylinder in the position of extension. At the end of 6 weeks weight bearing was permitted, and after 10 weeks there was only slight residual swelling and tenderness over the anterior compartment. She exhibited full flexion, but lacked 5° of full extension. She has since regained full extension, and she walks and dances without any trace of disability.

SUMMARY

The mechanism and treatment of fractures of the tibial spines are discussed, with a review of the literature, and 5 cases are presented.

Conservative treatment by closed manipulation, followed by a cylinder cast, is recommended in all but the exceptional cases. The technic of open and closed reduction is described.

reveal the bone injury, but even here, caution must be observed. In the anteroposterior view, the displacement may hardly be noticeable, and in the lateral aspect, the avulsed portion may not offer heavy enough calcification to be at all conspicuous unless the films are of good quality and are studied with care. A hazy film will often be misinterpreted, but in a good film the osteochondral fragment can be clearly seen lifted from its bed in the tibial plateau (Fig. 2).

CLOSED REDUCTION

Treatment of anterior-spine fractures may often be very simple. In cases in which displacement is slight, or in which there is no displacement, nothing is required except a stove-pipe plaster cast well applied. Theoretically, this does not wholly limit rotation of the tibia on the femur, but complete immobilization does not seem to be necessary. The cast should be maintained for five to seven weeks, depending on the severity of the injury.

FIGURE 3 Tunnel Suture of Insertion of Anterior Crucial Ligament

During this interval full weight bearing should be encouraged. In the more severe cases, in which the avulsed fragment has broken loose so that it is tilted upward into the knee joint, a general anesthetic must be given, but here, again, the fragment can usually be manipulated back into place by simple extension of the lower leg. If the displaced fragment fails to respond to this maneuver, Clarke⁹ has described the use of gentle rotation of the tibia on the femur to stretch the crucial ligament and thus to disengage the bony fragment, after which extension of the knee serves to complete the reduction. An even more forcible maneuver may sometimes be required, as in Case 2. Here it was necessary for the operator (H. K. M.) to press with both thumbs on the two sides of the patellar tendon until he felt he was able to catch the edge of the

fragment and depress it enough for it to fall back into place when the knee was extended.

OPEN REDUCTION

Although most authors believe that closed manipulation will succeed in reducing these fractures, Roth¹ has insisted upon open reduction. His reasons would seem more convincing if they were not controverted by the general experience of many other surgeons. He believes that the anterior attachment of the lateral meniscus is displaced by the avulsion in such a way that it folds under the bony fragment and obstructs reduction. "From my experience at operation," he says, "it is clear that what prevents the fragment from being replaced is the lateral meniscus. Until this is divided, no replacement is possible." That this cannot be true is proved by the fact that Clarke was able to reduce all 10 of the cases in his series by simple, closed methods. "Extension under anaesthesia will always reduce the fracture," he states, and again, "we have never found it necessary to resort to operative treatment." Four of our cases confirmed Clarke's dictum, and in the fifth, which we opened under a mistaken diagnosis, we found the avulsed fragment lying free, with the meniscus offering no impediment to reduction. Nevertheless, Roth's observation should be borne in mind, for it will explain failures in reduction that might occur.

MacAusland¹⁰ and Lee¹¹ have argued in favor of open reduction on the grounds that the fragment can be replaced more accurately, the fixation will be more secure, and recovery will be more speedy. In their postoperative care, plaster casts are maintained for three weeks as against five to seven weeks by the nonoperative technic. The formidable risk of wide surgical exposure of a knee joint does not seem to us to justify the small advantage gained by this operation in routine cases. Nevertheless, each surgeon will judge for himself. Sever¹² observes: "I am not at all convinced that early operation for repair of that particular type of fracture (tibial spine) is necessary, wise, or even efficient, and I don't think the results are as good and the risks certainly are greater."

For a surgical approach our own preference is for the parapatellar type of exposure, with the original incision beginning as in a simple knee-cartilage operation, and with extension of the incision as much as may be needed.

Once the joint has been opened, the semilunar cartilage should be inspected and if damaged removed. The tibial avulsion itself can usually be replaced with ease. Lee¹¹ has advocated suturing it in place, and MacAusland¹⁰ has recommended screw fixation. Compere's fracture textbook illustrates the method of drilling a tunnel and suturing, which we have found to be both useful and easy. A bit is drilled obliquely upward from a point about 2.5 cm beneath the tibial plateau and 1 cm

to the side of the tibial tubercle. The bit emerges in the floor of the cavity from which the bony fragment was avulsed. A second hole is drilled parallel to the first and No. 2 chromic catgut is then threaded up through one hole, matted through the fragment and brought down through the other hole to be tied over the tibial bridge (Fig. 3). Any alternative method of fixation would probably be equally effective, and Roth¹ has even stated that no fixation is necessary, once the fragment has been reduced and the leg secured in extension. Certainly greater security can be felt after the joint is opened if the surgeon has anchored down his reduction with some form of fixation. A stovepipe plaster is then advisable for not less than three weeks, after which gradual knee motion should be resumed actively.

CASE REPORTS

CASE 1* E. B., a 22-year-old woman, could give no details of her accident except that she fell off her bicycle and in doing so felt a sudden pain in the right knee. She was treated at first for a sprain, but x-ray examination showed the fracture, consisting of a mild upward displacement of the anterior cruciate attachment with its osteochondral fragment. No reduction was necessary. A stove-pipe cast was applied for 4 weeks, and walking was allowed. The patient made a full recovery and when seen again at the end of 7 months had resumed full, normal activity, with no complaints whatever.

CASE 2. N. C., a 15-year-old boy, was thrown from his bicycle and was brought to the hospital with his left knee in about 15° flexion. He was unable to extend it or to bear weight. He could flex the knee to 90°. An attempt to test the cruciate ligaments proved so painful that it was not carried out in full. X-ray films revealed elevation of the anterior spine of the tibia, together with a moderately large fragment from the upper tibial epiphysis. An attempt was made to reduce this fracture under anesthesia. Full extension could not be obtained until the operator placed his right and left thumbs on either side of the patellar tendon and pressed in deeply as he manipulated the knee toward extension. A sudden snap was then felt, giving the impression that this misplaced fragment had been reduced. Full extension could then be easily obtained, and in this position a long leg cast was applied. The patient's postoperative course was uneventful. He was allowed on crutches on the 4th hospital day and was discharged on the 10th day, to be followed in the Out-Patient Department. The cast was retained for 3 weeks, after which he was allowed to walk on crutches without weight bearing. On his last visit, at the end of 3 months, he showed full, normal range of motion, and stated that he had no disability whatever. He was not limited in any way in his activity, and he had no pain.

CASE 3. C. W., a 29-year-old man, fell about 20 feet from a ladder and landed on his feet. At first he did not realize that he had been injured, but after 30 minutes there was a dull pain in the right knee, and he was unable to extend it fully. After 8 days, he came to the hospital. Flexion to 90° was readily obtained, but extension beyond 165° could not be carried out without severe pain. The patient localized his pain in the anterior compartment just behind the patellar tendon. X-ray films were regarded as normal though subsequent examination revealed the fracture with very slight displacement on the lateral view and none on the anteroposterior view. The patient was operated on under the diagnosis of probable torn cartilage. The anterior cruciate ligament with the tibial spine and a portion of the adjacent tibial plateau were found avulsed in a roughly quadrangular manner, and displaced upward into the anterior compartment of the knee. A tunnel suture was carried out by the technic described above. A plaster cast was applied and postoperatively x-ray films showed the fragment in good position,

with normal joint space. The patient proved particularly unco-operative, and in spite of all efforts, he persisted in keeping the knee rigid after the cast was removed at the end of 4 weeks. This continued for 3 months, and resulted in an almost completely stiff knee. Manipulation under anesthesia at the end of this time succeeded in flexing the knee to 90° without difficulty, but it is estimated that another 3 months will be required before normal motion is regained.

CASE 4. A. M., a 46-year-old man, was injured while shoveling dirt from the bottom of an 8-foot trench when the ground caved in and buried him up to the level of his knees. While he was thus immobilized, a chunk of tarred surface about 75 pounds in weight, slipped against his thigh so hard that he was thrown in a semicircle to the left and backward while his legs were still firmly planted in the gravel. After being freed, the patient was unable to walk, and his knee was swollen. X-ray examination revealed a fracture of the anterior tibial spine of the left knee. The knee could be fully extended without anesthesia, and a plaster cylinder was applied in this position. Quadriceps-setting exercises were permitted while the leg was in plaster. The cast was removed after 1 month. At the end of 12 weeks the patient walked with a slight limp. He still lacked 5° of full extension. Flexion was normal. After 16 weeks, there was no loss of extension or flexion, but some degree of quadriceps atrophy was still present.

CASE 5. P. A., a 14-year-old girl, was knocked off the bicycle that she was riding, and when her right foot struck the ground there was immediate pain in her right knee. In the course of the next few hours, the knee became markedly swollen, and she was unable to extend it. She was given a general anesthetic, and her physician manipulated the knee so that extension was obtained. After consultation an x-ray examination disclosed an avulsion fracture of the tibial spine, and the knee was then immobilized in a plaster cylinder in the position of extension. At the end of 6 weeks weight bearing was permitted, and after 10 weeks there was only slight residual swelling and tenderness over the anterior compartment. She exhibited full flexion, but lacked 5° of full extension. She has since regained full extension, and she walks and dances without any trace of disability.

SUMMARY

The mechanism and treatment of fractures of the tibial spines are discussed, with a review of the literature, and 5 cases are presented.

Conservative treatment by closed manipulation, followed by a cylinder cast, is recommended in all but the exceptional cases. The technic of open and closed reduction is described.

OTOLOGIC ASPECTS OF VERTIGO*

JOSEPH J FISCHER, M D †

BOSTON

VERTIGO is a very important word in the vocabulary of the otolaryngologist. Unfortunately, some confusion exists, regarding not only etiology but also definition and nomenclature. One has to bear in mind that vertigo is a subjective symptom that makes the physician entirely dependent on the history given by the patient, who may call the most variegated sensations vertigo. He not only describes the feeling of being turned around or of objects turning around, but also sensations of losing the ground or being lifted up, or lightness or heaviness in the head. Others complain of unsteadiness and fainting, and finally a great many call vertigo the various visual sensations such as blurring, double vision, jumbling of letters and vertical lines that appear oblique.

Hence the confusion in the nomenclature: turning vertigo, tactile vertigo, ocular vertigo, spatial vertigo, epileptic vertigo, hysterical vertigo, cardiac vertigo and so forth.

The same confusion holds for the numerous definitions of vertigo, some based on physiologic processes, and others on psychologic ones.

Vertigo can be elicited by all organs concerned with spatial consciousness: the peripheral labyrinth, central pathways, eyes and proprioceptive pathways. For the last, attention should be directed to the close relation of the labyrinth to the tonus of the body musculature.

For the otolaryngologist the two important questions pertaining to vertigo are whether labyrinthine and nonlabyrinthine vertigo can be differentiated, and whether, within the labyrinthine vertigo, the central and peripheral types can be differentiated.

Considering the fact that vertigo is not an objective symptom that can be ascertained by the physician or determined quantitatively like other functional tests and that there is no histologic proof for the anatomic pathways, it appears obvious that such a differential diagnosis cannot be made on a scientific basis. The question must therefore be approached from a clinical point of view based upon clinical experience of thousands and thousands of cases, hence the differential diagnosis must always be considered a tentative one. There is first the differentiation of labyrinthine and nonlabyrinthine vertigo. The former is rotational, directional or systematic, the latter is nonrotational, nondirectional and asystematic. The latter group comprises the various sensations of dizziness found in diseases of the cardiovascular system and the gastrointestinal tract, endocrine lesions, visual disturbances and

so forth. It is discussed in detail from the standpoint of internal medicine by Dr. Aisner.

Table 1 summarizes the differentiation of peripheral labyrinthine vertigo and central vertigo.

When one is taking the history of a patient with vertigo all leading questions must be strictly avoided, but if the patient himself mentions turning sensations spontaneously, his statement is of great importance.

Sham movements of surrounding objects are much more common than similar movements of the subject, the direction of the sham movements is the same as the fast component of the nystagmus.

Peripheral vertigo occurs in the form of attacks, such a spell usually lasts a minute or a few minutes. There are but few exceptions in which the attack may continue for hours with a peripheral lesion. Examples of this type are rupture of the window, hemorrhages and trauma. The clinical importance of a thorough history is demonstrated by the case of a patient with a chronic otitis media who has had repeated attacks of vertigo off and on over a long period. However, there is one spell he will never forget, he knows the exact date, even the exact hour when it occurred, and he knows also the direction of the moving objects. Such a history enables the clinician to arrive at the diagnosis of fistula of the horizontal semicircular canal, the establishment of the fistula coincides with this one severe attack of vertigo.

Peripheral vertigo is often brought about by sudden changes of the position of the head. It is a characteristic history when the patient complains about his first attack in the morning when he gets out of bed, it is the change from the recumbent to the vertical position. The second attack occurs when he washes his face, there again is the change of position when he bends his head.

Consciousness is never absent in peripheral labyrinthine lesions regardless of the intensity. Even with the most violent attack of vertigo, as mentioned above (window rupture), the patient will never lose his consciousness. Hence a loss of consciousness reported by the patient points rather toward a central lesion.

Spontaneous nystagmus is always present during an attack of vertigo caused by peripheral labyrinthine lesions, outside the spells, nystagmus may or may not be present, according to the underlying disease.

The course of peripheral labyrinthine vertigo is self-limited. In cases of labyrinthitis there exists in the beginning vertigo and nystagmus to the affected ear, increasing in intensity, with the destruction of the labyrinthine function, vertigo disappears (limited course). Should, however, the

*This paper and the following two papers were presented as a symposium on vertigo under the auspices of the Boston City Hospital, December 20, 1948.

†Junior visiting surgeon for diseases of ear and throat, Boston City Hospital.

infection spread beyond the boundaries of the inner ear, vertigo and nystagmus recur (now in the opposite direction), enabling the clinician to arrive at the diagnosis of meningitis of the posterior fossa, or cerebellar abscess. In central lesions vertigo starts, gradually increases in the further course and persists usually for the entire length of time.

The caloric reaction influences the spontaneous vertigo in cases of peripheral labyrinthine disease, whereas central lesions may not reveal any influence or some disproportion may exist between induced vertigo and induced nystagmus.

Disturbances of equilibrium in labyrinthine diseases show the character of the peripheral type—

Postconcussion states, both simple and complicated

Sea sickness and air sickness

Cardiovascular lesions showing either rotational vertigo as in vasomotor lesions of the end arteries, thrombosis of the inferior cerebellar artery and arteriosclerosis or nonrotational (described by Dr Aisner)

Vertigo can easily be understood as a symptom in such peripheral diseases as inflammatory, degenerative, toxic and traumatic conditions. It may however be difficult to explain the mechanism of vertigo for a number of lesions commonly summarized under the heading of vascular disturbances.

TABLE I Differential Characteristics of Peripheral Labyrinthine and Central Vertigo

TYPE OF VERTIGO	TURNING SENSATION	SPINAL MOVEMENTS OF SURROUNDING OBJECTS	OCCURRENCE OF VERTIGO	INITIATED BY MOTION	LOSS OF CONSCIOUSNESS	NYSTAGMUS	COURSE	AFFECTED BY CALORIC TEST	DISTURBANCE OF EQUILIBRIUM	SPONTANEOUS NYSTAGMUS	OTOSCOPIC FINDINGS	NEUROLOGIC FINDINGS
Peripheral labyrinthine	Rotational	Present	In attacks	Yes	None	Present	Self-limited	Yes	Peripheral type	Peripheral	Often positive	Negative
Central	Rotational lateropulsion	Absent	Continuous	No	Occasionally	Often absent	Persistent	No necessarily	Central type	Central type	Negative	Often positive

that is, falling in the direction of the slow component and changes in falling with changes in the position of the head. In central lesions the equilibrium shows disturbances of the central type—that is, independently of the position of the head.

Spontaneous nystagmus in labyrinthine lesions shows the peripheral type associated, horizontal-rotatory or rotatory-horizontal, medium in amplitude and frequency, and persistent. In central lesions the spontaneous nystagmus may be associated or dissociated, plain horizontal or rotatory or vertical, coarse in amplitude, slow in frequency and persistent or transient.

The otoscopic findings in peripheral diseases are often positive, such as acute or chronic otitis media, cholesteatoma, adhesive process and scars, whereas in central lesions the findings are usually negative.

The neurologic findings in peripheral diseases are mostly negative, whereas in central lesions they are often positive.

The following diseases are accompanied by vertigo

Labyrinthine and retrolabyrinthine disorders, including inflammatory, degenerative, toxic, traumatic, neoplastic and vascular lesions (Ménière's syndrome, angioneurotic crisis, allergy, migraine).

Central lesions particularly fast developing (inflammations, hemorrhages, multiple sclerosis—acute stage—and tumors) which display marked vertigo, whereas slowly developing processes such as multiple sclerosis, syringobulbia, chronic processes and slowly growing tumors show very little or no vertigo.

Ménière's syndrome is the most important in this group. A few of the many theories comprise disturbances of water, sodium or potassium metabolism and allergy as a basis of the lesion. In spite of the apparent contradiction all these theories assume more or less the same origin—namely, a retention of fluid, leading to extracellular edema. Since the labyrinth presents a cavity with stiff walls filled with fluid, the slightest cellular edema will raise the endolabyrinthine pressure. This, in turn, explains the attacks of vertigo, the tinnitus and the impaired hearing.

Angioneurotic crisis of the eighth nerve was first described by Kobrak¹. He assumed an increased permeability of the vessels of the labyrinth and of the choroid plexus. The clinical manifestations are almost the same as those in Ménière's syndrome.

Hyperactivity of the *carotid-sinus reflexes* was given by Soma Weiss² as a cause of clinical symptoms such as periodic attacks of vertigo, vasospasm, intestinal cramps and allergic reaction.

Allergy as a basis for the Ménière syndrome has long been assumed by many authors. The fact that elimination of certain foodstuffs improved the clinical condition and that the histamine skin test (Miles Atkinson³) was positive gives proof that at least some cases are allergic in etiology.

Migraine otique is the name given by Escat⁴ to the following clinical pictures: attacks of vertigo, spontaneous nystagmus, tinnitus, impaired hearing, headaches and hemianopsia. The underlying lesion has been described as a circulatory disturbance of the internal auditory artery, increased endocranial pressure or brain swelling.

In central lesions differentiation should be made between fast developing and slowly developing diseases. Although the former are always associated with vertigo, the latter show very little or no vertigo. The majority of otolaryngologists believe that vertigo is a frequent symptom of multiple sclerosis. This is an erroneous assumption since vertigo is only experienced in cases of acute exacerbations of multiple sclerosis.

In simple *post-concussion* lesions vertigo is often the only symptom, lasting for many years. It is very difficult for the otologist to answer the question whether vertigo is caused by an organic lesion, or whether it is of psychogenic origin. Positional nystagmus and the head-moving test are suggestive.

In the complicated post-concussion lesion — that is, *commotio cerebri* in addition to fracture of the skull — some other symptoms, such as headaches, fatigue, deafness or impaired hearing and tinnitus, are present.

In *sea sickness* and *air sickness* vertigo is associated with vasovegetative symptoms such as nausea, vomiting, perspiration, pallor, salivation and even diarrhea. The peripheral labyrinth is generally claimed as the site of the lesion. The observation that deaf mutes without labyrinthine function are not subject to sea sickness and the fact that sea sickness can be produced experimentally by imitation of the exact movements of the ship seem to favor this theory. However, there is one main symptom missing — namely, spontaneous nystagmus, which is characteristic of peripheral labyrinthine lesions. One theory explaining the lack of spontaneous nystagmus is propounded by Quix,⁵ who

assumes that sea sickness is caused by stimulation of the otolith apparatus.

In cardiovascular lesions one must differentiate the directional or true vertigo and the nondirectional or vague dizziness. To the former group belong the vasomotor disturbances of the internal auditory artery. It is difficult to locate the site of the vertigo, whether the peripheral labyrinth or the central labyrinthine pathways are involved. The same difficulty holds true for cases of thrombosis of the inferior cerebellar artery. Shuster⁶ describes a syndrome consisting of vertigo, loss of hearing of high-pitched tones and involvement of the vertical semicircular canals. He assumes arteriosclerotic changes of the artery supplying the vertical canals and the part of the cochlea concerned with the perception of high sounds.

For a detailed study on rotational vertigo the reader is referred to the book "The Inner Ear" by Fischer and Wolfson⁷ and for all the other forms of dizziness in cardiovascular and other diseases to the discussion of vertigo from an internal point of view presented by Dr. Aisner.

NEUROLOGIC ASPECTS OF VERTIGO

DEREK E. DENNY-BROWN, M.D.*

BOSTON

VERTIGO is a sensation, a symptom without any essential objective sign, and is therefore subject to all the limitations imposed by the descriptive powers and capacity for observation possessed by the patient. It is a subjective sensation of dis-equilibration and, whatever its origin, may be accompanied by nausea, vomiting and circulatory collapse when the vertigo is severe. It is obviously important to separate the symptom from the sense of uncertainty, often described as dizziness ("false vertigo") complained of by psychoneurotic patients, particularly in panic states, but this is in practice not difficult. The distinguishing characteristic of true vertigo is that the sense of apparent movement is consistent, occurs in clear-cut attacks and is made worse by movement.

The neurologist is chiefly interested in the decision whether a given complaint of vertigo has

origin in the labyrinth, the brain stem or the cerebrum. He is but little concerned with ocular causes, for they do not present vertigo as a primary disorder, and in such conditions as carotid-sinus syndrome and anemia the vertigo is usually non-specific and not a leading symptom. In the decision of the three usual situations of origin of true primary vertigo, the chief criteria used by the neurologist are the type of sensation, the form of the attack and the associated symptoms.

The type of sensation is infinitely variable. In the most clear-cut sensations of rotation, the direction of movement of objects should indicate the side of the lesion. A sinking sensation has no special significance, though its association with sudden limpness of the limbs may indicate involvement of the saccule or utricle ("the otolithic catastrophe" of Tumarkin[†]). Whether the patient feels that he

*Professor of neurology, Harvard Medical School, neurologist-in-chief, Boston City Hospital.

†Tumarkin A. Otolithic catastrophe: new syndrome. *Brit. M. J.* 2:175-177, 1936.

rotates or objects rotate around him has not been found of any value in the differential neurologic diagnosis

The most important criterion in my view is the *form of the attack*. Vertigo of labyrinthine origin is paroxysmal, beginning suddenly and maximally and then subsiding gradually. The attack should be brief—that is, lasting minutes or perhaps an hour or two—and should leave only a minor residual sensation of slight movement. Vertigo resulting from brain-stem lesions is by contrast more continuous, is made worse by movement and persists for hours or days at a time. Vertigo may occur at the beginning of an attack of epilepsy or migraine but is then transient, and does not persist after the remainder of the attack. If labyrinthine vertigo is sufficiently severe to be associated with other symptoms it outlasts them. Both peripheral and central vertigo may be related to change in posture, but, in my experience, this is more common in the central form.

The usual associated symptoms of peripheral vertigo are tinnitus and deafness, but these may be entirely absent for a long period after the first attacks of Ménière's disease. The most common associated symptoms of vertigo from brain-stem lesions are diplopia and other disorders of the cranial nerves such as numbness of the face, dysarthria and ataxia. I have seen loss of consciousness from peripheral vertigo, but only as syncope at the height of a very severe attack. It is also uncommon in central causes, except in epilepsy with vertiginous aura. If headache and vomiting are the first symptoms, a central cause must be suspected.

The neurologic disorders associated with vertigo are chiefly diseases of the brain stem. Tumors of the lateral recess (auditory neuromas) and cere-

bellar tumors are associated with vertigo only in about 50 per cent of cases. Distortion of the brain stem is then present. Multiple sclerosis is associated with vertigo when a recent patch of the disease involves the brain stem, with associated cranial-nerve palsy, ataxia and disorder of the long tracts, but the vertigo subsides with the end of the acute phase of the attack. Thrombosis of the posterior inferior cerebellar artery is also a cause, and occlusion of other vessels in the pons and medulla gives rise to transient episodes of vertigo and cranial-nerve palsy in patients liable to vascular disease. Chronic syphilitic meningitis can produce a characteristic syndrome of facial paralysis, deafness and vertigo from loculation in the lateral recess.

The investigation of vertigo involves not only a careful history and a close examination of labyrinthine function but also testing of the other cranial nerves. If weakness, numbness or ataxia of limbs is present the patient has usually complained of them. The best leads to a correct appreciation in a doubtful case are always to be gained from the history.

Treatment of the condition obviously depends upon the diagnosis. I have nothing to add that is not already common knowledge, but wish to emphasize the commonly remitting character of Ménière's disease, and the value of tiding over early attacks with small doses of phenobarbital. In my opinion, the more radical treatments have many disadvantages and should not be embarked upon unless the patient's livelihood is at stake and the condition clearly one-sided. Finally, I would warn against leaping to the conclusion that the patient is psychoneurotic simply because he is overanxious. A continuous uncertainty concerning the next moment when one may be flung to the ground can unnerve anyone.

VERTIGO AS IT CONFRONTS THE INTERNIST

MARK AISNER, M.D.*

BOSTON

THE term "vertigo" has been subjected to a great deal of abuse. It is not synonymous with "dizziness," which is an extremely common symptom encountered almost daily by the practitioner of general medicine. Vertigo implies a sense of rotation with reference to surrounding objects in space and a loss of the sense of equilibrium. The patient complaining of this symptom is aware of some difficulty in the postural mechanism, and has a feeling of insecurity, especially in the upright position, when a sensation of falling or veering to one side is present. It is often a disabling and alarming symptom, and one for which the patient will almost invariably seek medical attention. When resulting from disease involving the peripheral

labyrinth or auditory nerve, it is associated with tinnitus and deafness.

In contrast are a group of subjective manifestations variously referred to by the patient as dizziness, lightheadedness, giddiness, faintness, swimming sensation, fog before the eyes, blackout and so forth. Such symptoms are often seen in a variety of functional and organic disturbances, and should be differentiated from what is considered true vertigo. Differentiation is made possible by an accurate description of the sensations experienced by the patient, and by the evaluation of associated symptoms and underlying or predisposing conditions. From the standpoint of the internist, these subjective complaints are far more frequently encountered than true vertigo. Thus, they may comprise

*Assistant professor of medicine, Tufts College Medical School, junior visiting physician, Boston City Hospital.

part of the symptomatology of neurosis, cerebral arteriosclerosis, hypertension, various other cardiovascular disorders, endocrinopathies, infectious diseases, gastrointestinal disturbances, sudden changes in posture, blood loss, other conditions causing cerebral ischemia and so forth

Perusal of many of the modern textbooks of medicine readily demonstrates the common misuse of the term vertigo, when actually the subjective sensation of dizziness or one of its many equivalents is meant. Thus, vertigo is listed as a symptom of a host of medical ailments, among them cardiac arrhythmias, heart block, cardiac failure, carotid-sinus syndrome, hyperthyroidism, hypoglycemia, Addison's disease, anemias, menopausal syndrome and gastritis, to mention only a few. True vertigo is generally not encountered as part of the symptomatology of these disorders. Dizziness and its many variants, however, are quite common.

Apart from pure neurologic and otologic entities, the internist is apt to see vertigo as a manifestation of one of the following: hypertensive cardiovascular disease, leukemia and drug intoxication.

Occasionally, one encounters mild vertigo in patients with hypertensive cardiovascular disease, more commonly in women. It may be associated with tinnitus. In unusual cases the vertigo and tinnitus may occur as isolated severe attacks, and under such conditions may be mistaken for Ménière's syndrome. Such patients usually present a history of attacks after periods of excessive physical activity. Less commonly, in hypertension associated with arteriosclerosis, hemorrhage into the labyrinth may result in the sudden onset of severe vertigo, tinnitus and deafness.

Involvement of the middle ear, the internal ear and the auditory nerve in the acute and chronic leukemias, though uncommon, is well known. The pathologic processes include hemorrhage, leukemic infiltration and connective-tissue proliferation. Symptoms of vertigo, tinnitus and deafness result.

Intoxication with drugs such as quinine, quinidine, cinchophen and the salicylates may produce the symptoms of vertigo, tinnitus and decreased auditory acuity. This has been attributed to func-

tional impairment of the eighth nerve. The administration of streptomycin has frequently resulted in vestibular dysfunction and less commonly in deafness. The occurrence of such disturbed function is related to both the size of the dose and the duration of treatment. More recently, with the accepted lower dosage schedules for the treatment of streptomycin-sensitive infections, less difficulty with labyrinthine function has been experienced. However, patients on the same dosage of the drug differ considerably in their susceptibility to these so-called toxic manifestations. The rotary component of vertigo is often absent in these persons, although difficulty with the postural mechanism is characteristic. Frequently, they experience the sensation of overshooting the mark when a sudden movement is made. For example, in reaching for an object, the hand may continue its progress for several inches beyond the object, or rolling over in bed may convey the sensation of continuation of that act. The pathologic changes resulting in these symptoms have been localized by some to the ventral cochlear and inferior cerebellar nuclei, although recently additional disturbance in the peripheral mechanism has been postulated.

Vertigo not attributable to any of the causes already discussed falls into the realms of the neurologist and otologist, and may be a manifestation of disease of the labyrinth, the brain stem or the cerebrum. Under such circumstances, the internist, who is apt to see these cases first, must seek proper consultation. A history of recurring episodes of vertigo associated with fluctuating tinnitus and deafness may indicate Ménière's syndrome, which the internist may take upon himself to treat. In patients presenting vertigo as a symptom for the first time, consultation seems in order. Careful history taking and physical examination may be of value in the choice between neurologist and otologist. For example, persistent and progressive vertigo, disturbances in consciousness, memory defects and the presence of cranial-nerve palsies point to a lesion in the central nervous system and the advisability of neurologic consultation. The details of the otologic and neurologic aspects of vertigo have been discussed by Drs. Fischer and Denny-Brown.

THROMBOCYTOPENIC PURPURA ASSOCIATED WITH TUBERCULOUS SPLENOMEGALY AND TUBERCULOSIS OF THE BONE MARROW*

BENJAMIN A. GOULEY, M.D.† NATHAN BLUMBERG, M.D.‡ and REGINALD J. GRAYSON, M.D.§

PHILADELPHIA

WHEN splenectomy in thrombocytopenic patients has on occasion revealed the tuberculous origin of a splenic enlargement, the post-operative results have been dramatic. Surgical intervention has removed both a fatal tuberculoma and a serious blood dyscrasia.^{1,2} Further knowledge of this apparently rare combination will probably show that such a surgical cure is not to be anticipated in every case because of developments such as those reported below—namely, the association of “primary” tuberculosis of the spleen, thrombocytopenic purpura and a widespread tuberculosis of the bone marrow. We are unable to find a similar grouping of such lesions which almost certainly was the basis for the fatal thrombocytopenic purpura in the following case.

CASE REPORT

R. A., a 51-year-old Negro inmate of the Eastern State Penitentiary previously in good health, complained on August 5, 1947, of lumbar pain radiating toward the right buttock and posteriorly down the right thigh. Also he stated that he had lost 25 lb. (the weight dropping from 195 to 168 lb.) in 5 months.

Physical examination revealed a hypertensive status but was otherwise negative. Later the sciatica disappeared but pain appeared in the left upper quadrant of the abdomen. Attention was further drawn to the patient's complaints when a tonsillectomy was postponed because of a bleeding time of 30 minutes. On November 26, 1947, re-examination disclosed that the spleen was palpable and very firm; the prostate was enlarged and hard but elastic. X-ray examination of the chest and pelvis did not reveal pulmonary or bone disease. The prostatic enlargement was diagnosed as hypertrophy of the prostate.

Fever and prostration developed in the latter part of November and from then until death on January 14, 1948, the temperature showed a septic fluctuation ranging from 96 to 102°F. The red-cell count remained fairly stable ranging from 4,200,000 to 5,850,000 but early in January, in spite of a transfusion of 600 cc. of blood and continuous iron and liver therapy, the count dropped sharply. On January 11 examination of the blood showed a red-cell count of 5,000,000 and a white-cell count of 8900 with 78 per cent neutrophils, 21 per cent lymphocytes, 1 per cent myelocytes and occasional normoblasts. The platelet count was 100,000. Another platelet count and a bone-marrow biopsy were ordered but unfortunately could not be done. The lungs remained clear. The liver was enlarged, and the spleen extended down to the umbilicus and was slightly tender. Increasing hemorrhages from the nose and mouth, perineal eruptions on both arms and the presence of numerous erythrocytes in the urine preceded the patient's death.

§Attending physician, Eastern State Penitentiary.

An autopsy, performed by Drs. Charles Swalm and Benjamin Gouley at the Coroner's Office of Philadelphia, the conjunctivas showed moderate icterus; purpuric spots were visible on the arms and the trunk in spite of the dark skin; a black bloody secretion was present in the nose and mouth.

The lungs were normal aside from terminal congestion and edema. The liver was large, pale and soft, with numerous milium tubercles beneath the capsule and throughout the parenchyma. The spleen was greatly enlarged, weighing 950 gm. The capsule was roughened and nodules milium.

FIGURE 1. Conglomerate Caseous Tuberculosis of the Bone Marrow (from the Middle Portion of the Sternum).

Large cell dark stained is seen at 10x, in small adjacent tubercle. Bone trabecula is seen at lower left (x 200).

and larger were visible through it. Section showed pale-yellow caseous nodules ranging in size up to a nail dollar. The intervening pulp was dark and so.

The stomach and small intestine were filled with dark blood. The adrenal glands were normal as was the pancreas. A few scattered milium tubercles were noted in the cortex of the left kidney. The urinary bladder showed congestion of the mucosa over the trigone with some small tubercles. The right lobe of the prostate was enlarged to the size of a lemon and filled with large caseous nodules conglomerate with caseation in the adjacent seminal vesicle.

No bone lesion was noted on gross examination. However on decalcification of numerous bone sections preparation for histologic examination it was noted that the marrow substance showed grayish-white infiltrations, generally small and patchy but in some areas solid, homogenous and waxy.

Death was due to massive gastrointestinal hemorrhage in connection with a widespread purpura. His pathological examination of the liver disclosed numerous milium tubercles. The intervening parenchyma showed an inflammatory reaction. The Kupfer cells were swollen and the liver cords separated in many fields by edema.

into which many polymorphonuclear leukocytes had infiltrated. The periportal tissue also showed a cellular infiltration composed of many monocytes and polymorphonuclear leukocytes, but there was no increase of fibrous tissue and no biliary-duct hyperplasia.

The spleen showed extensive caseation. There was a marked hemorrhagic infiltration around most of the caseous areas, infiltrating them, undergoing an acute hyalinization and merging in many fields with the caseation. The splenic follicles were not hyperplastic, but there was a moderate reticuloendothelial hyperplasia lining the sinusoids. The latter contained erythrocytes and monocytes of various types. No megakaryocytes were found.

Sections from three ribs (fourth, fifth and sixth left, adjacent to the costochondral junction) and from the mid-portion of the sternum all showed widespread miliary-tubercle invasion, and marrow hyperplasia in the intervening non-caseous areas. Conglomerate caseation replaced the original marrow structure in many low-power fields in sections from each of six paraffin blocks (Fig. 1). Typical giant cells of the Langhans type were numerous and were found even in the small submiliary foci of early caseous coalescence (Fig. 2). Although numerous tubercles impinged on the bony trabeculae, the latter were scarcely involved. In many areas they remained undamaged despite the complete disappearance of the marrow and its replacement by caseation. In only

the center and the periphery of the cell. Other giant cells showed a peculiar ring-shaped deposition of the chromatin (Fig. 3). They were remote from caseous areas, and could be differentiated from the Langhans giant cell of caseation by their structural and staining aspects. They were considered to be degenerate megakaryocytes.

Staining for acid-fast organisms in paraffin sections revealed well stained tubercle bacilli in the caseous lesions of the spleen,

FIGURE 3 *Megakaryocyte, Degenerate Form (?), with Large Giant Cell, Remote from Caseous Lesions and Clear Basophilic Cytoplasm.*

one or two fields was there characteristic fragmentation under osteoclastic attack.

In the bone-marrow hyperplasia, erythropoiesis predominated. Megaloblasts and especially normoblasts crowded the fields. Granulopoiesis was rather diminished, and in some fields scarcely noted. Normal megakaryocytes were absent. However, there were many large giant cells, irregularly round, with clear basophilic cytoplasm. They contained a hyperchromatic nucleus of varied shape, generally, it was a tangled skein of dense black structure covering both

the prostate and seminal vesicle, and numerous but poorly stained bacilli in the bone marrow.

DISCUSSION

Purpura has long been recognized as an occasional complication of pulmonary and nonpulmonary tuberculosis.³⁻⁵ Its pathogenesis was obscure for many years. In 1911 Cannata⁶ postulated an adrenal insufficiency with consequent loss of vascular tone. Bauch² (1916) referred to a toxic degeneration of vascular endothelium, and Pratsicas⁷ (1924) to a cutaneous and intestinal embolism in the course of tuberculous bacillemia. The latter explanation made miliary tuberculosis a necessary precursor of the purpura.

The role of the spleen in this type of purpura was previously unknown or ignored as in the report of Pratsicas, in which the purpura in 4 patients was accompanied by gastrointestinal hemorrhage in 3, and by splenic enlargement in all, proved at autopsy to be tuberculosis of the spleen. This finding was obscured by the emphasis placed on miliary tuberculosis as the basic cause for the purpura. "Primary" tuberculosis of the spleen does not necessarily lead to purpura. The latter was noted only twice in the 50 cases collected by Winternitz.⁸ In fact, the interesting combination of splenic tuberculosis and thrombocytopenic purpura has been reported only three times,^{1, 2, 9} the diagnosis

having been made after splenectomy or at autopsy. Earlier observers were unaware of thrombocytopenia, and it is likely that many previously cited cases of purpura in tuberculosis were identical with the case reported above. No purpuric patient today would be studied without platelet counts and bleeding-time determination. These may give the only diagnostic clue, since on exceptional occasions a tuberculous spleen of clinical significance may be only slightly enlarged, and therefore not palpable. In the case reported by Weiner and Carter² the spleen weighed 237 gm and was not palpable before operation. In Kellert's¹ patient, a splenomegaly was noted, the organ weighed 1050 gm. In most cases of "primary" or "isolated" tuberculosis of the spleen, the enlargement is an outstanding physical sign.

The term "primary tuberculosis of the spleen" was introduced many years ago by Winternitz,⁵ who emphasized its limitations. However, it is useful thus to characterize a striking splenomegaly, in many cases of extraordinary size—the organ weighing as much as 3780 gm¹⁰ and filled with massive or conglomerate tuberculous caseation, the basis of symptoms and the ultimate cause of death of the patient. This is in contrast to the insignificant and incidental tuberculous splenitis without splenic enlargement sometimes encountered at autopsy in tuberculous patients.

As originally noted, the term "primary" does not signify portal of entry or even the initial site of tuberculosis. In primary tuberculosis of the spleen it is almost certain that a primary extra-splenic involvement has long since healed and a latent splenic focus has gradually assumed clinical importance. This must account for the fact that the large majority of patients so involved are adults. Primary tuberculosis of the spleen may clinically be the only discoverable tuberculous lesion. Often, it is accompanied by tuberculosis elsewhere, which, however, is nonpulmonary in at least 50 per cent of patients. In all cases the pathologist finds a miliary invasion of the liver, via portal transport, secondary to the splenic lesion. In the case reported above there was also an important genitourinary involvement, probably a concurrent development. We have pointedly ignored it, emphasizing instead the involvement of the spleen and bone marrow, which certainly was the cause of the patient's hemorrhagic tendency and finally of his death. However, in passing, it should be pointed out that recognition of the tuberculous nature of the patient's genitourinary disease would possibly have led to a similar conclusion concerning the splenomegaly.

At autopsy the osseous system showed nothing of note. In view of the microscopical finding of bone-marrow involvement, the absence of tuberculous osteitis and periostitis was striking. The occurrence of miliary tuberculosis of the bone marrow has recently been reported¹¹ but we are

unaware of such widespread involvement as noted in this case with so little bone destruction.

In fields not replaced by caseation or precaseous inflammation, the bone marrow was hyperactive. The concentration of normoblasts was notable. Polycythemia has been recorded in cases of tuberculous splenomegaly.¹⁰ Our patient at first had a moderate secondary anemia, his acute anemia in the last month of life was due to hemorrhage and toxicity and possibly to a myelophthisic factor because of marrow caseation. The absence of normal megakaryocytes was probably a toxic reaction to tuberculosis—not only to systemic infection but more so, we believe, to the local bone-marrow involvement.

This patient did not have "myelofibrosis," a myelopathy in which bone-marrow elements are replaced by fibrous tissue, with compensatory extramedullary hematopoiesis in other organs of the reticuloendothelial system. It has been emphasized that myelofibrosis, previously known as a reaction to toxemia and bone-marrow irritation of various types, may also follow systemic miliary tuberculosis.¹² The spleen may or may not be involved in the tuberculous process, and although the organ is often moderately enlarged, it is decidedly not the splenomegaly known as "primary tuberculosis of the spleen." None of the 4 patients with myelofibrosis associated with tuberculosis recently reported by Crail, Alt and Nadler¹² exhibited thrombocytopenic purpura. In contrast, our patient did not show evidence of myelofibrosis or of the accompanying widespread visceral fibrosis, which seems to constitute a chronic cellular reaction peculiar to some types of miliary tuberculous infection.

Tuberculosis of the bone marrow was almost certainly a factor in this case of thrombocytopenic purpura. To what extent it governed or influenced the purpura can only be determined by future observation of similar cases, it will be interesting to see not only what information can be gleaned by bone-marrow biopsy but also what splenectomy can offer in the presence of tuberculous myelitis. This may be a new field for streptomycin therapy.

In addition, 2 cases of "primary" tuberculosis of the spleen with purpura have been seen in the last two years in the large post-mortem experience at the office of the coroner of Philadelphia. These three patients were adult Negroes. Death resulted from gastrointestinal hemorrhage. The second case showed, as did the first, a tuberculous myelitis in the sternum and in many ribs. Unfortunately, a similar study of the bone marrow was omitted in the third case. Previously reported purpura in tuberculosis has presumably been in white patients. Our own experience indicates that colored patients with fever, splenomegaly, purpura and other hemorrhagic manifestations form a group in which tuberculosis of the spleen, thrombocytopenia and bone-

into which many polymorphonuclear leukocytes had infiltrated. The periportal tissue also showed a cellular infiltration composed of many monocytes and polymorphonuclear leukocytes, but there was no increase of fibrous tissue and no biliary-duct hyperplasia.

The spleen showed extensive caseation. minutes after meals. Her blood pressure was 158/80, and on vaginal examination the uterus was consistent with a 3 months' gestation. The blood serologic findings were negative, the blood was Group "A" and Rh+. Throughout this pregnancy her blood pressure varied from 150/90 to 160/90, and she complained of constant heartburn with nausea coming on while she was lying down. Urinalyses were within normal limits. On May 19, 1948 she began vomiting brownish coffee-ground material at night and noted tarry stools and weakness. She volunteered the information that the nausea and vomiting

minute Hematemesis and melena persisted, the stools being strongly positive for blood. Two 500-cc blood transfusions were given. On May 28th a gastrointestinal series (Fig 1) was interpreted as follows:

There is a single fetus of approximately 8 months in age, presenting by vertex, with the occiput to the left. There is a diaphragmatic hernia. There is no peptic ulcer or gastric carcinoma. After 5 hours there is still some barium in the bernal pouch.

On May 29 the hemoglobin was 72 per cent, and the red-cell count 3,700,000.

On the same day a vaginal cesarean section was performed under spinal anesthesia with the aid of a Schuchardt incision. A 5-pound, 8-ounce, normal living male infant was delivered from the left occipitoposterior position by rotation and extraction with Kielland forceps. The patient received a third 500-cc blood transfusion after operation and was kept in Fowler's position postoperatively. Her postoperative course was uneventful, with no heartburn or nausea, the stools becoming negative for occult blood on the 3rd postoperative day, and the highest temperature being 99.6°F. She and her infant, who then weighed 5 pounds, 12 ounces, were both discharged from the hospital in good condition on the 11th postoperative day.

When seen on July 12 the patient had no complaints. Examination disclosed a well healed perineum giving good support with no cystocele or rectocele. The cervix was clean and presented healed anterior and posterior incisions. The uterus was well involuted and normal in size, contour, position and mobility. There were no adnexal masses or tenderness. On November 8, 1949, a gastrointestinal series showed no evidence of diaphragmatic hernia.

SUMMARY

A case of strangulated diaphragmatic hernia in pregnancy with survival of mother and infant, is reported.

The literature on diaphragmatic hernia as a complication of pregnancy is briefly reviewed.

STRANGULATED DIAPHRAGMATIC HERNIA COMPLICATING PREGNANCY*

Report of a Case

GEORGE A. BOURGEOIS, M.D.† AND WILFRED T. HOOD, M.D.‡

MARLBOROUGH, MASSACHUSETTS

DIAPHRAGMATIC hernia is not a rare complication of pregnancy. By roentgenologic examination Rigler and Eneboe¹ demonstrated this condition in 25, or 12.8 per cent, of 195 women in the last trimester of pregnancy, in 4, or 5.1 per cent, of 71 primiparas, and in 21, or 18.1 per cent, of 116 multiparas. They reached the conclusions that diaphragmatic hernia is commoner in the female than in the male, that its incidence increases with age and repeated pregnancy and that increased intra-abdominal pressure is an important etiologic factor. Mengert and Murphy² showed that intra-abdominal pressure is increased by voluntary muscular effort during labor.

Although relatively common during pregnancy, diaphragmatic hernia is seldom responsible for major symptomatology. It is generally recognized as a cause of persistent and intractable pyrosis and other minor gastrointestinal symptoms, characteristically aggravated by the horizontal and relieved by the upright position.³ But the few cases of strangulation recorded in the literature spell a high incidence of tragedy. Maternal deaths are reported in the ante-partum period by R. O. Muller⁴ and by Keim, Rosenthal and Hugier,⁵ in the intra-partum period by Granzow⁶ and by Diddle and Tidrick,⁷ and in the post-partum period by Legry.⁸ Maternal survivals are recorded by Salgado⁹ (cesarean section early in labor), by DeLee and Gilson¹⁰ (strangulation occurring post partum and responding to conservative treatment) and by Thompson and Le-

Blanc¹¹ (intra-partum strangulation with successful post-partum operation).

In the case reported below the patient experienced pyrosis throughout the greater part of two pregnancies. During the last ten days of her second pregnancy strangulation of the diaphragmatic hernia was manifested by hematemesis and melena. The diagnosis was established by x-ray examination. Definitive management of the problem was predicated on reduction of intra-abdominal pressure by prompt evacuation of the uterus without labor, spinal block being employed as the anesthesia of choice. Evacuation of the uterus was accomplished by vaginal cesarean section because the infant was small, and an extraperitoneal procedure promised a clean peritoneal cavity if surgery directed at the diaphragmatic hernia became necessary. Fortunately, the hernia underwent spontaneous reduction after delivery.

CASE REPORT

Mrs. N. T., a 31-year-old secundigravida, had begun her last normal menstrual period on August 30, 1947, her expected date of confinement being June 6, 1948.

Except during her pregnancies the patient had always been well. She had had no serious illnesses, no operations and no injuries. The menarche had occurred at 12 years of age, and her periods had been regular, occurring about every 28 days and lasting 4 or 5 days with moderate flow and no pain. The family history was irrelevant.

The patient had delivered spontaneously at term a 3-pound, 13-ounce, male infant on November 19, 1941. Throughout this pregnancy she had complained of severe heartburn, and at times of puffiness about the hands and face. She was kept on a low-salt diet during the last 2 months of gestation. On admission to the hospital for delivery her blood pressure was 156/90, and urinalysis showed slight albuminuria. The infant survived.

The patient was first seen on November 30, 1947. She complained of heartburn and nausea occurring about 30

minutes after meals. Her blood pressure was 158/80, and on vaginal examination the uterus was consistent with a 3 months' gestation. The blood serologic findings were negative, the blood was Group "A" and Rh+. Throughout this pregnancy her blood pressure varied from 150/90 to 160/90, and she complained of constant heartburn with nausea coming on while she was lying down. Urinalyses were within normal limits. On May 19, 1948, she began vomiting brownish coffee-ground material at night and noted tarry stools and weakness. She volunteered the information that the nausea and vomiting

minute. Hematemesis and melena persisted, the stools being strongly positive for blood. Two 500-cc blood transfusions were given. On May 28th a gastrointestinal series (Fig. 1) was interpreted as follows:

There is a single fetus of approximately 8 months in age, presenting by vertex, with the occiput to the left. There is a diaphragmatic hernia. There is no peptic ulcer or gastric carcinoma. After 5 hours there is still some barium in the hernial pouch.

On May 29 the hemoglobin was 72 per cent, and the red-cell count 700,000.

On the same day a vaginal cesarean section was performed under spinal anesthesia with the aid of a Schuchardt incision. A 6-pound, 8-ounce, normal living male infant was delivered from the left occipitoposterior position by rotation and extraction with Kielland forceps. The patient received a third 500-cc blood transfusion after operation and was kept in Fowler's position postoperatively. Her postoperative course was uneventful, with no heartburn or nausea, the stools becoming negative for occult blood on the 3rd postoperative day and the highest temperature being 99.6°F. She and her infant, who then weighed 5 pounds, 12 ounces, were both discharged from the hospital in good condition on the 11th postoperative day.

When seen on July 12 the patient had no complaints. Examination disclosed a well healed perineum giving good support with no cystocele or rectocele. The cervix was clean and presented healed anterior and posterior incisions. The uterus was well involuted and normal in size, contour, position and mobility. There were no adnexal masses or tenderness. On November 8, 1949, a gastrointestinal series showed no evidence of diaphragmatic hernia.

MEDICAL PROGRESS

ENDOSCOPY*

EDWARD B. BENEDICT, M D †

BOSTON

PROGRESS in endoscopy during the past two years has been marked by an improvement in diagnostic methods. These, in turn, have been aided by the use of new instruments. It seems fitting that this article should be devoted to a survey of the technical advances and to a re-emphasis of some of the important aspects of endoscopy.

BRONCHOSCOPY

This is such a well established procedure in the diagnosis and treatment of bronchopulmonary disease that one might think there would be little that was new to report. However, improved technic by the use of the Broyles‡ broncho-

cancer-cell study (Papanicolaou¹) By the use of this method Gibbon et al² report a very high incidence of positive results in carcinomas inaccessible to direct visualization by bronchoscopy, and negative to cancer-cell sputum study. Their results are reviewed in Table 1 and 2.

My own experience in a study of 309 proved cases of primary bronchogenic carcinoma reveals that bronchoscopic biopsy was positive in 189 cases (61 per cent), and that in 5 additional cases cancer cells were found in the secretions aspirated at the time of bronchoscopy. With improved technic in washing out of the bronchus leading to the area under suspicion, cancer cells may be found more frequently.

At the risk of repetition and at the risk of pointing out what to many is obvious, I emphasize again the indications for bronchoscopy. This procedure is of real assistance in establishing a diagnosis when symptoms exist such as cough, hemoptysis and wheeze. Unfortunately, this diagnostic aid is not always used when indicated. Furthermore bronchoscopy should be performed in cases of bronchial obstruction, atelectasis, tuberculosis, lung abscess, bronchiectasis, tumor and foreign body.

The importance of bronchoscopy in hemoptysis when x-ray examination may be negative or inconclusive should be particularly emphasized. In a recent case in which hemoptysis was the presenting

Neoplastic cells found bronchoscopy completely negative	43	36

scope makes the introduction of the instrument easier for the patient and the visibility better for the bronchoscopist. The Broyles bronchoscope, having an expanded lumen proximally, permits the operator to visualize the vocal cords very easily without the aid of the cumbersome laryngoscope, and the patient is subjected to less discomfort when the bronchoscope is introduced into the trachea. The visibility is further increased by improved lighting and by the use of foroblique, right-angle and retrograde telescopes for inspection of the various bronchial orifices that are beyond the reach of the straight bronchoscope. Biopsies may be taken in the usual manner or with special forceps provided for use in conjunction with the foroblique telescope. Tumors or stenoses of the upper-lobe orifices, invisible by direct bronchoscopy, may be readily visualized by the use of the right-angle telescope.

Another major advance in bronchoscopic technic is the special method of aspirating secretions for

symptom x-ray films were taken on several occasions and were said to be essentially normal or to show some bronchiectasis. Everybody seemed satisfied and bronchoscopy was not suggested by any of three physicians until nine months had elapsed. At the time of bronchoscopy a carcinoma of the right main bronchus was easily demonstrated, and biopsy obtained. Fortunately, the lesion appeared to be favorable for pneumonectomy which was successfully carried out a few days later. Since several similar cases have come to my attention

recently, I consider it of the greatest importance to stress the value of bronchoscopy in hemioptysis

ESOPHAGOSCOPY

In this field of endoscopy, the most important point to emphasize is one that is by no means new but is far too often neglected by the medical profession. Reference is made to the use of a previously swallowed thread as a guide to bougienage and sometimes as a guide to esophagoscopy. As long as a patient can swallow water, he can swallow a thread (No 1 white silk), and thus keep a lumen open. If the lumen is not kept open it all too often shuts down very suddenly and completely. Such a complete stoppage frequently occurs when least expected, many weeks after live ingestion or during or after radiation therapy for carcinoma. Just prior to complete stoppage the physician in charge, and also the patient, may be lulled into a false sense of security by the latter's ability to take liquids or even very soft solids. The esophagoscopist, as well as the patient, is very much "up against it" when there is absolutely no lumen whatever and no thread to guide the way. It is admitted that occasionally a lumen can be re-established by very gentle probing with a small bougie used under direct vision through the esophagoscope, and also that intravenous therapy with improved hydration sometimes results in a spontaneous reopening of a lumen, but the wise physician should never wait for this eventuality. Therefore in the early stages of a live stricture or preliminary to radiation therapy for carcinoma of the esophagus, he should *instruct the patient to swallow a continuous No 1 white silk thread*, at the rate of about 15 cm per hour, keeping the spool in his breast pocket, and cutting off the distal end as it appears at the anus, and, secondly, he should *call in a competent esophagologist*.

Another point worth emphasizing is that in a patient suspected of having carcinoma of the esophagus, one negative biopsy does not exclude it. At least one more biopsy should be obtained from deep within the lumen of the narrowed area.

GASTROSCOPY

The development of the Benedict operating gastroscope** has opened a new field for positive gastroscopic diagnosis. With this instrument it is possible to aspirate secretions (and thus to permit better visualization of the stomach) and to obtain biopsies for accurate microscopical diagnosis. This instrument was first used in March, 1948, and since then 50 biopsies have been obtained with the positive microscopical diagnoses listed in Table 3. There have been no accidents or complications.

One of the most valuable uses of gastroscopic biopsy is in the diagnosis of lymphoma. From the gross appearance alone when viewed through the

gastroscope, lymphoma is readily mistaken for gastritis or diffuse infiltrating carcinoma. Therefore, the obtaining of a biopsy is of very great importance. A positive biopsy is more valuable than a negative biopsy, but when one is dealing with a diffuse process a negative biopsy, adequately taken from a representative area, should go a long way toward excluding lymphoma. A positive biopsy definitely clinches an otherwise impossible diagnosis.

In the diagnosis of carcinoma of the stomach, when doubt exists from the clinical, laboratory and x-ray standpoint, a positive gastroscopic biopsy

TABLE 3 Microscopical Diagnoses of Specimens Obtained with Benedict Operating Gastroscope

DIAGNOSIS	NO OF CASES
Gastritis (all types and degrees)	24
Normal stomach	13
Inadequate specimen	6
Carcinoma	2
Carcinoma or lymphoma (later proved to be lymphoma)	1
Lymphoma	1
Cystic dilatation and edema	1
Total	50

is of great importance. A negative biopsy does not exclude carcinoma.

In spite of the great increase in knowledge of gastritis since the development of the Wolf-Schindler,⁴ flexible gastroscope, the surface has barely been scratched in attempts to correlate the clinical, radiologic, gastroscopic and pathological findings in gastritis.^{5, 6} From the 50 biopsies already taken and studied by Dr Tracy B Mallory and me, it is apparent that much remains to be done in determining the limits of normal gastric histology, and in classifying the type and severity of gastritis. It is probable that postoperative gastritis does not exist as a separate entity. Thick folds do not necessarily mean gastritis. Reddening, edema and adherent secretion may be present in a gastric mucosa that shows no significant histologic change. On the other hand, there may be pathological evidence of gastritis in a stomach that looks normal to the endoscopist.

This relatively easy method of gastric biopsy is thus already of clinical importance and will eventually lead to a better understanding of gastric histopathology.

PERITONEOSCOPY

In this field of endoscopy no new instruments have been developed, but I wish to emphasize the increasing value of the procedure, which permits positive diagnosis of carcinoma of the liver, carcinomatosis, tuberculous peritonitis, abdominal and pelvic tumors, unexplained ascites and so forth without laparotomy. In many cases it saves unnecessary exploratory laparotomy. Furthermore, it can be safely performed on patients who are too

*Manufactured by the American Cystoscope Makers Incorporated New York City

sick to justify major surgical procedures, but in whom it is important to obtain a positive diagnosis. Biopsy specimens can and should be obtained in almost all cases.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE ONE HUNDRED AND SIXTY-EIGHTH ANNIVERSARY

May 24, 25 and 26, 1949

THE one hundred and sixty-eighth anniversary of the Massachusetts Medical Society was observed at the Worcester Memorial Auditorium in Worcester on May 24, 25 and 26, 1949.

Twelve hundred and thirty physicians, 224 exors and 100 ladies were registered. The Supervising Censors met in Room E at the Hotel Sheraton on May 23 at 4 30 p m. This meeting was followed by the Cotting Supper in the Ballroom of the Hotel Sheraton, which was attended by 207 councilors. The annual meeting of the Council followed this supper at 7 00 p m, with 203 councilors in attendance, as recorded in the attendance books.

TUESDAY, MAY 24

The first general session opened at 9 00 a m in the Little Theater of the Auditorium under the co-chairmanship of Dr John J Dumphy and Dr Bancroft C Wheeler.

The one hundred and sixty-eighth annual meeting of the Society was held in the Little Theater at 11 00 a m. President Daniel B Reardon presided. The attendance was about 150. Dr Reardon spoke on "The State of the Society," after which the annual oration, "Some Responsibilities of Medical Education," was delivered by Dr C Sidney Burwell. (This lecture appeared in the June 9 issue of the *Journal*.) The annual luncheon was served on the stage of the Auditorium to 135 fellows.

The second general session was held in the Little Theater at 2 00 p m under the co-chairmanship of Dr Edward P Bagg and Dr Donald Munro.

WEDNESDAY, MAY 25

The third general session was held at 9 00 a m under the co-chairmanship of Dr George R Dunlop and Dr Fred H Allen. The Shattuck Lecture was delivered at 11 05 a m by Dr Paul D White, of Boston, on the subject, "La Médecine du Cœur." (This lecture appeared in the May 26 issue of the *Journal*.)

At noon certain of the sections held their luncheons, followed by their annual meetings. The Section of Medicine, under the chairmanship of Dr Laurence B Ellis, met on the stage. The attendance was 89. The Section on Pediatrics met in the Assembly Room under the chairmanship of Dr W Bradford Adams. The attendance was 48. The Section on Radiology, under the chairmanship of Dr Albert M Moloney, met in the Male Chorus Room with 40 in attendance. The Section on Physical Medicine met in the Musicians' Room, under the chairmanship of Dr David C Dittmore, with 38 in attendance.

At 2 00 p m the fourth general session was held in the Little Theater under the co-chairmanship of Dr Donald B Cheetham and Dr Lawrence R Dame.

The annual dinner was held in the Ballroom of the Hotel Sheraton at 7 00 p m with 439 in attendance. The speaker of the evening was Roscoe Pound, LL D, University Professor Emeritus of Harvard University and former dean of Harvard Law School, who delivered an address entitled, "The Professions in the Society of Today."

THURSDAY, MAY 26

The fifth general session was held in the Little Theater at 9 00 a m under the joint chairmanship of Dr James T Brosnan and Dr Norman B McWilliams.

At noon the remaining scientific sections held their luncheons and meetings. The Section of Surgery met on the stage under the chairmanship of Dr Robert E Gross, with 27 in attendance. The Section of Obstetrics and Gynecology met in the Male Chorus Room, under the chairmanship of Dr James F Conway, with 40 in attendance. The Section of Dermatology and Syphilology, under the chairmanship of Dr Francis P McCarthy, met in the Female Chorus Room with 30 in attendance. The Section of Anesthesiology met in the Assembly Room, under the chairmanship of Dr Morris J Nicholson, with 40 in attendance, and the Section

on Physiology and Pathology, under the chairmanship of Dr Monroe J Schlesinger met in the Musicians' Room with 37 in attendance

The sixth general session was held at 2:00 p m under the co-chairmanship of Dr George L Schadt and Dr John F Casey

An exhibition of works of art by members of the Massachusetts Physicians' Art Association was on view throughout the meeting

The special list of officers, standing and special committees councilors censors admissions and deaths is appended

H QUIMBY GALLUPE, *Secretary*

ANNUAL MEETING OF THE SOCIETY

The one hundred and sixty-eighth annual meeting of the Massachusetts Medical Society was called to order by the president, Dr Daniel B Reardon, in the Little Theater of the Memorial Auditorium in Worcester at 11:00 a m on May 24

Dr Reardon introduced Dr John J Dumphy, the retiring president of the Worcester District Medical Society, who spoke as follows

Worcester is very happy to welcome the meeting of the Massachusetts Medical Society for the third time in one hundred and sixty-eight years. We are glad to have you see our medical facilities, our library and our city. We have had our local committee working in co-operation with the state committee for many months to make this meeting a success. We hope you will enjoy yourselves.

The President then introduced the honorable Charles F Jeff Sullivan, lieutenant governor of the Commonwealth, and mayor of the City of Worcester, who addressed the meeting as follows

It is indeed a real privilege and a pleasure to extend official and personal greetings on the occasion of your one hundred and sixty-eighth annual meeting.

Worcester, its citizens and I as its mayor, and Massachusetts and I as its lieutenant governor, are honored at the selection of the heart of the Commonwealth for the annual conferences and sessions of the Massachusetts Medical Society. And in behalf of all of the citizens, I bid you a hearty welcome. Worcester and the Commonwealth are proud of the national and international distinction and reputation of our physicians. They are proud that our physicians have achieved in the noble profession of medicine the advancement of medical science, brought comfort to the afflicted, prolonged life expectancy and turned despair into confidence and hope.

In the prevention and cure of disease that ravages the body and mind of man, remarkable progress has been made. Study and research continue without abatement to relieve suffering humanity. Your intense unselfish efforts are to be commended and encouraged. You of the medical profession have a glorious tradition of centuries, a heritage that must be preserved and enhanced.

Worcester and Massachusetts salute you, the members of the Massachusetts Medical Society, and are grateful for your individual and collective service to your fellow men.

We bid you godspeed in your constant efforts in searching out the cause, prevention and cure of disease that bring worry and misery to the human race. Your destiny and your duty you have always recognized, and you have proved faithful to your sacred trust.

I know that, true to your profound oath, you will carry on in the highest, noblest tradition of your chosen profession.

The Secretary submitted the record of the 1948 annual meeting, held on May 25, 1948, as published in the July 29, 1948, issue of the *New England Journal of Medicine*, and moved its acceptance. The motion was seconded and so voted.

The President then called upon Dr Edward P Bagg, chairman of the Committee on By-laws and Council Rules, who addressed the meeting as follows

The Secretary informs me that the printed copies of the proposed changes in the by-laws have been distributed. I should like to offer some final corrections, as they were approved last night at the Council meeting.

On the first page, the resolution regarding Chapter IV, Section 3, is corrected by the substitution of the word "to" for the word "under," and the insertion of the word "on" before the word "by-laws."

Likewise, later in the same chapter, the words "to the" should be substituted for "under."

Otherwise, the copy as printed in the circular is correct. The corrections have already been approved by the Council. I move that the proposed changes in the by-laws be adopted by the Society.

The motion was seconded, and it was so voted.

The Secretary reported on the membership of the Society as follows

The membership in May, 1948, was 6538. This has increased by 304 new members admitted since then, in addition to 6 re-instatements, bringing it to a total of 6848. Losses were 6 by deprivations, 30 by resignation and about 60 by death, which brings the sum total to 6752 members as of May 24, 1949.

A motion to approve the report was offered and seconded, and it was so voted.

At the request of the President, the vice-president, Dr Donald Munro, assumed the chair and Dr Reardon gave the following address

Again, as for many generations past, the Society meets to review the accomplishments of another year. I venture to state that never in our long and eventful history have we passed such a period as the last twelve months. For today our task is not the simple one of progress in the field of medicine. Rather, it is the hutching of a professional fortress against what has seemed to us to be the attack of our own government. Never in the memories of those of us long in practice have the conditions obtained that have confronted us during the tenure of office of those who now yield up their duties to the hands of the incoming officers. I like to believe that we have met this challenge in our time. I know that we have done our best not to fail the thousands of our fellows who have placed their cause in our hands. I speak the gratitude of all of us to our permanent officers, who in their help and guidance have made this year one of which the Society may well be proud.

A brief recital of achievement is due to you. Thus, I should like to review the work of several of our departments in particular that you may realize that the torch has been borne by willing hands for all.

The Committee on Public Relations has been active as usual. Public relations was stimulated this year by the incorporation of the Massachusetts Health Conference, the first meeting of which was held at the Hotel Statler, Boston, on February 19 and 20, when about 1000 people, both lay and professional, participated. This conference was the result of activity by the chairman of the Massachusetts Medical Society Committee on Public Relations who stepped down from the chairmanship and formed a conference of which Dr John F Conlin was elected president. As Dr Conlin stated "At no time previously has there been a mass, concentrated attempt here to bring consumers and distributors of health services—

sick to justify major surgical procedures, but in whom it is important to obtain a positive diagnosis. Biopsy specimens can and should be obtained in almost all cases.

A motion to approve the report was offered and seconded, and it was so voted

At the request of the President, the vice-president, Dr Donald Munro, assumed the chair and Dr Reardon gave the following address

Again, as for many generations past, the Society meets to review the accomplishments of another year I venture to state that never in our long and eventful history have we passed such a period as the last twelve months For today our task is not the simple one of progress in the field of medicine Rather, it is the buttressing of a professional fortress against what has seemed to us to be the attack of our own government Never in the memories of those of us long in practice have the conditions obtained that have confronted us during the tenure of office of those who now yield up their duties to the hands of the incoming officers I like to believe that we have met this challenge in our time I know that we have done our best not to fail the thousands of our fellows who have placed their cause in our hands I speak the gratitude of all of us to our permanent officers, who in their help and guidance have made this year one of which the Society may well be proud

A brief recital of achievement is due to you Thus, I should like to review the work of several of our departments in particular that you may realize that the torch has been borne by willing hands for all

The Committee on Public Relations has been active as usual Public relations was stimulated this year by the incorporation of the Massachusetts Health Conference, the first meeting of which was held at the Hotel Statler, Boston, on February 19 and 20, when about 1000 people, both lay and professional, participated This conference was the result of activity by the chairman of the Massachusetts Medical Society Committee on Public Relations who stepped down from the chairmanship and formed a conference of which Dr John F Conlin was elected president As Dr Conlin stated "At no time previously has there been a mass, concentrated attempt here to bring consumers and distributors of health services —

the people who are receiving and the people who are doing—together for an exchange of information. Its success was indicated by the conference's unanimous vote to continue with a similar session a year hence." The reaction to this conference was widespread, and many states have written asking for details. We believe this to have been a step in the right direction of good public relations.

The great work of the *New England Journal of Medicine* has gone forward with ever-increasing success. We are fortunate in Dr. Joseph Garland. Scholarly and able, he maintains the circulation at its highest point in history. Well over 6000 copies go to the fellows of the Society in good standing. Fourteen thousand others go to regular paid subscribers all over the world. Over 4000 additional subscriptions go to students who will follow us. Nearly 500 more go to the entire membership of the New Hampshire Medical Society, and exchanges are in effect with 185 other medical journals, all of which go to the Boston Medical Library. The operation of this enterprise is marked by very real leadership and vision, and the *Journal* is a major factor among the influences that make the Commonwealth the medical center that it is. We rejoice in its continuing success and applaud the men who make that success possible.

This meeting marks the end of the first full year of our new permanent secretary. His task has been primarily to correlate work of the various committees of the Society to the end that conflicts in meetings may be eliminated, to see to it that developments in the national and state picture are made available to district societies and to conduct the office in Boston so that it functions at maximum efficiency with a greatly increased load. Deadlines have been established for committee reports, that the Council might have all matters pertinent to its deliberations in its hands in proper shape by meeting day. Co-ordination between the secretaries of the various district societies has been heightened by their gathering together for the discussion of mutual plans and problems. A new directory of fellows and a new edition of the by-laws are in process of publication. Office routine has been improved by the introduction of modern office methods and machines to cope with the added tasks presented by our growing membership. The attention to duty and the initiative exhibited by the Secretary should command the respect that is due him for his efforts over these last months. In departing my office I am most happy to know that my successors have no reason for worry whatsoever in the splendid work of Quimby Gallupe.

And what a performance the Director of Medical Education has turned in! I state it as a fact that we owe him a debt that unfortunately many, many of our members will never appreciate. Tireless, fearless, he has carried the story that must be told to every corner of the Commonwealth. Speaking seven days a week, often three and four times a day in widely separated localities in Massachusetts, he has fought the fight that is ours. In the service clubs, before Chambers of Commerce, on Beacon Hill, he has striven to repair our relations with the public. That they were in sad need of such repair no one can doubt. That we have the man for the job is susceptible to even less doubt. I say that John Conlin has been a task force all by himself that only those who have watched his work closely can truly appreciate. It will be a sad day for the Society if he ever leaves us. I commend him publicly as he should be commended. No man in my memory has done more for us.

Our work has carried us forward in other fields. Again this year as before we have sponsored the Postgraduate Assembly at Sanders College, so-called. We have been able thereby to bring to busy practitioners the renovation of methods and techniques that keeps the doctor abreast of the rapid progress in his field. The attendance has been exceptionally good, the results are felt in every town where our students care for patients. It is a highly laudable work, and those who plan for and govern its program, most particularly Richard Ohler, contribute to the community the share that is worthy of the true physician. The assemblies are ever better, and the enterprise now well established by us will continue.

The Treasurer's report is available to you, and a quick review should convince you that we are reasonably pros-

perous, as indeed we should be. The loyalty of our fellows in financial matters is traditional with us, and I am glad to testify to its continuance.

The work of all our numerous committees has progressed apace. The members have been faithful, and tribute is due also to them, for on our sustaining committees depends in large measure our ability to function as we should.

We have been materially assisted in recent months by the continued growth of our woman's auxiliary. There are twelve district auxiliaries now functioning with an organization totaling over 1000 wives of physicians. It is hoped to complete the organization of auxiliary societies in every district by the fall. There is much that has already been done by the ladies, and there is very much more that can be done particularly in the field of work in the secondary schools leading to the choice of medicine and nursing by the students as a career. The help thus rendered us can be invaluable in many spheres in the future.

I wish to emphasize one forward step that has been taken this year relative to our headquarters. In October, 1948, I was in receipt of a communication from Ludlow Griscom, a moving force in the plans for the Museum of Science that is to be constructed in Boston on the 6 acres located at the base of the Charles River basin. He suggested the possibility of the Society's taking over a wing in the new building, which is to be a substantial one. As a result, at my request, the Committee on Society Headquarters has held a number of helpful conferences with the trustees in charge of the project, and it is not beyond the realm of possibility that out of these exploratory meetings may come a solution of the problem of space that has plagued us for some time. I urge upon the Council and our successors a thorough examination of this matter in which may lie for us a very satisfactory answer to our need for a better home.

I desire also to refer to our participation in the growing work of the Blue Cross and Blue Shield. With the devotion to his job that seems to me to characterize so many of our workers, Dr. James C. McCann, president of the Massachusetts Medical Service, has helped provide the physician's answer to those who would engulf us. While Blue Cross ran into serious financial difficulties some time back, which resulted in the transfer of a number of Blue Cross-Blue Shield Groups to commercial coverage unfortunately obstructing enrollment activities of both corporations, the present outlook is once again favorable, and it is anticipated that a steady increase in growth is now well under way. Dr. Charles G. Hayden, executive director of the Medical Service, has recently emphasized to me two significant amendments in the Blue Shield by-laws voted at the last meeting of the members of Blue Shield to the effect that the president of Blue Shield shall be a physician and that the Board of Directors shall consist of from 15 to 21 members. The first amendment was a precautionary measure, whereas the second permits the introduction of younger physicians into the Blue Shield Board of Directors that there may always be continuity of medical experience and guidance. Also, changes have recently been made in the type of contracts afforded the public, with the thought that the broader coverage offered will provide an answer to some of the objections to the older type of contract that have been voiced from time to time. The growth of our voluntary health plans is a necessity for us in these days, and, therefore, I am happy to report to you the progress in both organizations which I have just mentioned.

There are just a few thoughts that, as your retiring president, I should like to leave with you. It is first of all impossible for me to thank by name all those whom I should like to mention. Time does not permit that I do so, and many of the more retiring of our collaborators do their work quietly and without general acclaim. That is as they wish it, and I respect their wishes. One cannot serve a year in the position that I have occupied without acquiring a rather definite philosophy on matters that involve us. I admit that my own feelings are colored by my own forty-six years as a physician. However that may be, bear with me a moment longer, and let us test our position in the life of the Commonwealth. I claim

that we have a real fight on our hands and that we need fighters to engage in the battle. Somewhere along the line our morale has slipped a bit. Our men, and in particular our younger men, must realize that if we have battled a bit more on some of these national programs than they like the long view indicates that we have battled for them. I referred earlier to the poor public relations of the doctor. Can there be any doubt that our doctors in a sense are farther from the people than they were thirty and forty years ago? The advances in the science that is our mistress are awe inspiring to those of us trained at the turn of the century, but the practice, infinitely more skilled now than then, seems colder, more dollar minded and somewhat less sympathetic, and the people know it. That they know it constitutes our great problem. True it is that organized medicine so-called has made its mistakes, but the safeguards offered the public in our organizations far transcend in importance the mistakes that we have made. Now if it be, as I believe it is, that societies such as ours have an obligation to the public greater than what we owe ourselves, it follows that our actions should be those of a society and not of individuals. But that I do not mean that we should endeavor to place limitations on the right of individual fellows to express their thoughts on public matters that are also medical matters. I do mean, however, that individuals so expressing themselves should have in their turn a due respect for the opinions of other physicians as expressed through the medical societies. To create by individual public statement a belief in the public mind that substantially greater division exists among doctors on the Administration's program regarding us as embodied in the bill now pending in Congress than actually exists is to do great disservice to the Society and others like it, to the profession and to the people themselves. In the course of my term, I have traveled to many of the district-society meetings throughout the Commonwealth, I have talked to individual physicians by the score, and I have seen this council, which one would ordinarily consider the proper forum on debate of matters medical, unanimously approve the fight that we are making in conjunction with other state societies against the socialization of medical practice. I have witnessed the response in our own society to the much debated assessment. Thus, I think I know as well as anyone present the sentiments held by our Massachusetts medical men on these questions. In consideration of that knowledge I judge that we have a right of protest when the policies of the Society are described in terms that would make of them minority policies in the people's mind.

One further word that I would say is this: if in our years of existence we have progressed on broad lines as a Society it has been so because of the interest of our members in our aims and objectives. I suggest it as a personal responsibility of our fellows that they pay close attention to what is going on and that they take upon themselves a larger share of the work of the Society, of which there is enough available, I can assure you. The officers at headquarters are not in essence a nest of empire builders. As I have seen, they are the group of men charged with the representation of the Society before the public and with the delivery to the Society of the type of service to which our members are entitled. The size of our membership requires large delegations of authority for speedy and efficient action, but we remain as democratic as in the earlier days. We shall continue so conditional only on the maintenance of the high level of interest by the membership. You may rest assured that your officers will look always to you for advice and counsel. In particular to you younger members do I wish to underscore the remarks that I have just made.

So it is that I end my service to you. When I entered upon the office of president a year ago I pledged you that I would do my utmost to so conduct my term that I might turn over the affairs of the Society to my successor in a condition that was just a bit improved over that which existed when I took over. I have spared no effort in that regard. It is, gentlemen, a great honor to have served in an office graced by the names that have preceded mine for a hundred and sixty-seven years. I trust you believe I have not failed you. To you all I give my thanks at this end of a most eventful year.

The President resumed the chair and asked the Secretary to show slides of the proposed location of the Boston Museum of Science on the Charles River at the dam.

The Secretary presented the slides, with a description of the location and the buildings, one of which might be the new home of the Society, the *New England Journal of Medicine* and the Boston Medical Library. The whole project was being considered by the Committee on Society Headquarters and would be presented more specifically at a future meeting of the Council of the Society.

The President then requested the Secretary to read the list of fellows who joined the Society in 1899 and were still active, and asked those present to come forward and receive a gold pin as a memento of the occasion. The Secretary read the following list of names:

Dr Theodore Bacon
Dr Frederick S Burns
Dr Lincoln Davis
Dr Richard Elv
Dr Eugene E Everett
Dr Patrick A Grady
Dr Joseph F Howard
Dr Arthur C Nason
Dr Edwin B Nielsen
Dr Luther G Paul
Dr Ralph W Place
Dr Mortimer J Stoddard
Dr Frank T Woodbury

The President then called for the delegates from other New England State Societies. The delegate from Connecticut, Dr Robert A Goodell, was the only one present, and Dr Reardon invited him to the platform. Dr Goodell spoke as follows:

It is again a great honor and privilege to come here and to bring the greetings and cordial good wishes of the members of the Connecticut State Medical Society. Dr Sprague, the president-elect, and Dr Sam Harvey, the retiring president, have both sent their personal greetings, as well as Dr Creighton Barker, our executive secretary, and I am sure that I bring the good wishes of all the members of our society.

You have a fine program. I was here last year, and I enjoyed it so much that I finally teased them into sending me again.

The President called for Dr James Faulkner to come to the platform to present the Society awards to medical students. Dr Faulkner spoke as follows:

Last year the Society voted to award a prize to a fourth-year student in each of the medical schools in the Commonwealth who best exemplified the qualities that go to make up the good physician. The task and responsibility of selecting a prize and of selecting students to receive these prizes was turned over to the Committee on Medical Education, and I am speaking in behalf of Dr Keefer, the chairman of that committee, today. Dr Keefer had to be in western Ontario today.

In selecting a suitable prize, the Committee had a good deal of discussion, and I think were very fortunate in

what they were able to do. They decided that a book would be an appropriate prize, and they have selected a de luxe edition of the *Symposium of Hematology*, which was written in honor of Dr. George Minot, a distinguished member of this society, Nobel Prize winner, and each volume is appropriately inscribed by the officers of the Society and is autographed by Dr. Minot. This volume contains Dr. Minot's original work on the use of extract of liver in pernicious anemia. That was the easiest task of the committee.

Selecting the students who best exemplified the intangible qualities that make up a good physician was a very difficult task. The committee handed it over to the deans of the three medical schools, and I had to act in a dual capacity there. The deans, in turn, consulted with members of their faculties in an attempt to measure rather intangible values.

There were many, many students to whom these awards might have been made. I am sure that the students who are receiving them this morning are representative of the highest type of material that is being put out from the medical schools of the Commonwealth, and it gives me great pleasure to announce the recipients of these awards from Boston University, Sylvan Baer, from Harvard University, Henry S. Harvey, and from Tufts College, William H. Ellswood.

Dr. Reardon explained that the books were autographed by Dr. George Minot, and contained a bookplate signed by the president and the secretary of the Society.

Dr. Reardon presented a book to each of the three students. He then told the audience that a devoted fellow of the Society had donated a fund to be used, in succeeding years, to purchase similar awards.

The President then introduced the newly elected officers of the Society. To Dr. Arthur W. Allen, the new president, he presented a copy of Robert's *Rules of Order* and an inscribed gavel.

Dr. Allen thanked the President for the gifts and then told the meeting of his first technical error in not asking for approval of his appointments at the Council meeting the evening before. Motion was made from the floor to approve Dr. Allen's appointments. The motion was seconded, and it was so voted.

Dr. Reardon then introduced Dr. C. Sidney Burwell, dean of Harvard Medical School, who delivered the one hundred and forty-first annual oration, "Some Responsibilities of Medical Education."

At the close of the oration, Dr. Reardon declared the one hundred and sixty-eighth annual meeting adjourned at 12:45 p.m.

APPENDIX NO. 1

OFFICERS FOR 1949-1950

President Arthur W. Allen, Boston, 266 Beacon St.
President-Elect Leland S. McKittrick, Brookline, 1180 Beacon St.
Vice-President Albert A. Hornor, Brookline Office, Boston, 319 Longwood Ave.
Secretary H. Quimby Gallupe, Waltham Office, Boston, 8 Fenway.
Treasurer Eliot Hubbard, Jr., Cambridge, 29 Highland St.
Assistant Treasurer Norman A. Welch, West Roxbury Office, Boston, 520 Commonwealth Ave.
Orator John W. O'Meara, Worcester, 390 Main St.

COMMITTEES ELECTED BY THE DISTRICTS

Executive Committee of the Council — Established 1941 (members *ex-officio* and one councilor and alternate elected by the councilors of each district medical society)
PRESIDENT Arthur W. Allen, Boston, 266 Beacon St.
PRESIDENT-ELECT Leland S. McKittrick, Brookline, 1180 Beacon St.
VICE-PRESIDENT Albert A. Hornor, Brookline Office, Boston, 319 Longwood Ave.
SECRETARY H. Quimby Gallupe, Waltham Office, Boston, 8 Fenway.
TREASURER Eliot Hubbard, Jr., Cambridge, 29 Highland St.
ASSISTANT TREASURER Norman A. Welch, West Roxbury Office, Boston, 520 Commonwealth Ave.

Term Expires 1950

BERKSHIRE Helen M. Scoville, Pittsfield, Pittsfield General Hospital (Alternate C. T. Leslie, Pittsfield, 18 Bank Row).
FRANKLIN Lawrence R. Dame, Greenfield, 78 Federal St. (Alternate Frank W. Dean, East Northfield, 185 Main St.).
HAMPDEN Archibald J. Douglas, Westfield, 30 Court St. (Alternate Frederic Hagler, Springfield, 20 Maple St.).
MIDDLESEX NORTH William M. Collins, Lowell, 174 Central St. (Alternate Artemas J. Stewart, Lowell, 310 Merrimack St.).
NORFOLK Charles J. E. Kickham, Jamaica Plain Office, Brookline, 1101 Beacon St. (Alternate Carl Beare, Boston, 483 Beacon St.).
WORCESTER NORTH John J. Curley, Leominster, 89 West St. (Alternate George P. Keaveny, Fitchburg, 62 Fox St.).

Term Expires 1951

ESSEX SOUTH Albert E. Parkhurst, Beverly, 1 Monument Sq. (Alternate Edwin D. Reynolds, Danvers, 48 High St.).
HAMPSHIRE Maurice T. Kennedy, Hadley, 11 Middle St. (Alternate L. Beverley Pond, Easthampton, 115 Main St.).
MIDDLESEX SOUTH Joseph C. Merriam, Framingham, 198 Union Ave. (Alternate John F. Casey, Brighton Office, Boston, 475 Commonwealth Ave.).
NORFOLK SOUTH Robert L. Cook, Quincy, 1245 Hancock St. (Alternate William R. Helfrich, Quincy, 272 Southern Artery).
SUFFOLK Harvey A. Kelly, Winthrop, 200 Pleasant St. (Alternate William E. Browne, Boston, 587 Beacon St.).
WORCESTER John Fallon, Worcester, 10 Institute Rd. (Alternate Nicholas S. Scarcello, Worcester, 1 Seldon St.).

Term Expires 1952

BARNSTABLE Harold F. Rowley, Harwichport. (Alternate Donald E. Higgins, Cotuit, Main St.).
BRISTOL NORTH William M. Stobbs, Attleboro, 63 Bank St. (Alternate Milton E. Johnson, Attleboro, 33 Bank St.).
BRISTOL SOUTH Curtis C. Tripp, New Bedford, 416 County St. (Alternate John C. Corrigan, Fall River, 422 North Main St.).
ESSEX NORTH Arnold P. George, Haverhill, 31 Summer St. (Alternate Frederic N. Sweetser, Merrimac, 19 Main St.).
MIDDLESEX EAST Thomas P. Devlin, Stoneham, 34 Pleasant St. (Alternate Robert Dutton, Wakefield, 33 Avon St.).
PLYMOUTH Charles D. McCann, Brockton, 12 Cottage St. (Alternate Alton L. Hurlburt, East Bridgewater, 81 Central St.).

Subcommittee on Blue Cross-Blue Shield Problems

Charles J. E. Kickham, Norfolk, *chairman*, Paul M. Butterfield, Barnstable, John Fallon, Worcester, Harvey A. Kelly, Suffolk, Joseph C. Merriam, Middlesex South.

Committee on Nominations — Established 1874 (one councilor and alternate elected yearly by each district medical society)

BARNSTABLE Harold F. Rowley, Harwichport. (Alternate Donald E. Higgins, Cotuit, Main St.).
BERKSHIRE Helen M. Scoville, Pittsfield, Pittsfield General Hospital (Alternate C. T. Leslie, Pittsfield, 18 Bank Row).

BRISTOL NORTH Joseph L. Murphy, Taunton 23 Cedar St (Alternate Curtis B. Kingsbury, Taunton 65 Prospect St.)

BRISTOL SOUTH Harold E. Perry, New Bedford 159 Cottage St (Alternate William Mason, Fall River, 151 Rock St.)

ESSEX NORTH Charles F. Warren Amesbury 155 Main St (Alternate Percy J. Look, Andover, 115 Main St.)

ESSEX SOUTH DeWitt S. Clark, Salem, 2 Oliver St (Alternate Harrison G. Pope, Swampscott, 90 Humpbrex St.)

FRANKLIN Warren D. Thomas Montague Central St. (Alternate Kenneth H. Rice, South Deerfield 141 Main St.)

HAMPDEN George L. Schadt, Springfield, 44 Chestnut St. (Alternate George L. Steele, Springfield 20 Maple St.)

HAMPSHIRE Joseph R. Hobbs, Williamsburg, Main St. (Alternate L. Beverley Pond, Easthampton, 115 Main St.)

MIDDLESEX EAST Edward M. Halligan Reading 37 Salem St. (Alternate John M. Wilcox, Woburn, 6 Bennet St.)

MIDDLESEX NORTH James Y. Rodger, Lowell, 226 Central St. (Alternate William M. Collins, Lowell 174 Central St.)

MIDDLESEX SOUTH (Alternate Fred R. Jouett, Cambridge, 1 Craigie St.)

NORFOLK Albert Ehrenfried, Boston, 520 Beacon St. (Alternate Carleton E. Allard, Dorchester, 428 Columbia Rd.)

NORFOLK SOUTH Nabum R. Pillsbury, South Braintree, Norfolk County Hospital (Alternate William R. Helfrich, Quincy, 272 Southern Artery.)

PLYMOUTH Peirce H. Leavitt, Brockton 147 West Elm St. (Alternate John C. Angley, Brantville, School St.)

SUFFOLK Conrad Wesselboeft, Boston 315 Marlboro St. (Alternate Charles C. Lund, Boston, 20 Gloucester St.)

WORCESTER Frank B. Carr, Worcester 27 Elm St. (Alternate George W. Ballantine, Worcester, 27 Elm St.)

WORCESTER NORTH John J. Curley, Leominster 89 West St. (Alternate Clarence A. McPeak, Fitchburg 18 Hartwell St.)

Committee on Public Relations — Established 1939 (one councilor elected yearly by each district medical society, the president and president-elect of the Society are chairman and vice-chairman respectively, and the vice-president and secretary of the Society are members *(ex-officio)*)

BARNSTABLE Harold F. Rowley, Harwichport

BERKSHIRE Patrick J. Sullivan, Dalton, 471 Main St

BRISTOL NORTH Milton E. Johnson, Attleboro, 53 Bank St

BRISTOL SOUTH Milton T. MacDonald, New Bedford, 99 Clinton St

ESSEX NORTH Harold R. Kurth, Lawrence, 57 Jackson St

Berkshire

C T Leslie, Pittsfield, *supervisor*
 M A Gangemi, North Adams
 H G Mellen, Pittsfield
 T H Nelligan, Pittsfield
 G S Wickham, Lee

Bristol North

J L Murphy, Taunton, *supervisor*
 J N Brewster, Attleboro
 C B Kingsbury, Taunton
 A J Leddy, Taunton
 H G Vaughn, Attleboro

Bristol South

C C Persons, New Bedford, *supervisor*
 Herschel Heinz, New Bedford
 W F MacKnight, Fall River
 E A McCarthy, Fall River
 E L Merritt, Fall River

Essex North

L C Peirce, Newburyport, *supervisor*
 J M Barry, Lawrence
 A B Consentino, Haverhill
 W G Thompson, Andover
 P E Zanfagna, Lawrence

Essex South

S N Gardner, Salem, *supervisor*
 W R Irving, Gloucester
 C A Palladino, Lynn
 E D Reynolds, Danvers
 J R Shaughnessy, Salem

Franklin

J E Moran, Greenfield, *supervisor*
 F J Barnard, Greenfield
 J P Collieran, South Deerfield
 H A Rys, Turners Falls
 E C Thorn, Greenfield

Hampden

John Pallo, Westfield, *supervisor*
 E W Beauchamp, Springfield
 A A Palermo, Springfield
 L A Putnam, Holyoke
 J L Smead, Springfield

Hampshire

L B Pond, Easthampton, *supervisor*
 Stephen Brown, Northampton
 M E Cooney, Northampton
 T F Corriden, Northampton
 J E Hayes, Northampton

Middlesex East

T P Devlin, Stoneham, *supervisor*
 C R Baisley, Reading
 H A Bouve, Wakefield
 R E Miltzer, Woburn
 S H Moses, Winchester

Middlesex North

L F King, Lowell, *supervisor*
 Harry Black, Lowell
 C L Brennan, Lowell
 G E Carriel, Lowell
 E H Latham, Lowell

Middlesex South

H J Crumb, Lexington, *supervisor*
 W O Blanchard, Newton
 H K Bloom, Everett
 E A Gaston, Framingham
 Dudley Merrill, Cambridge

Norfolk

K S Snow, Boston, *supervisor*
 G L Doherty, Boston
 I R Jankelson, Boston
 W C Moloney, Boston
 H A Novack, Brookline

Norfolk South

F A Bartlett, Wollaston, *supervisor*
 Arthur Rapoport, Quincy
 H S Reid, Cohasset
 R E Ross, Braintree
 W L Sargent, Quincy

Plymouth

R E Swenson, Plymouth, *supervisor*
 G L Fuller, Brockton
 S E Peterson, Brockton
 R F Welch, Brockton
 E E Wiesner, Brockton

Suffolk

L M Hurxthal, Boston, *supervisor*
 T J Anglem, Boston
 J F Collins, Revere
 R L Goodale, Boston
 J J Todd, Boston

Worcester

J W McKeon, Worcester, *supervisor*
 E J Croce, Worcester
 Thomas Hunter, Shrewsbury
 H L Kirkendall, Worcester
 E L Richmond, Worcester

Worcester North

K J Jolma, Gardner, *supervisor*
 F X Dufault, Athol
 E R Pickwick, Fitchburg
 F R Pierce, Gardner
 C A Wheeler, Leominster

Essex South — Thomas B Rafferty, Lynn
 Franklin — Kenneth Jacobus, Turners Falls
 Hampden — George D Henderson, Holyoke
 Hampshire — Robert C Byrne, Hatfield
 Middlesex East — George R Murphy, Melrose
 Middlesex North — Leonard C Dursthoff, Lowell
 Middlesex South — Horace P Stevens, Cambridge
 Norfolk — David D Scannell, Boston
 Norfolk South — George D Dalton, Quincy
 Plymouth — Arthur W Carr, Bridgewater
 Suffolk — Charles H Bradford, Boston
 Worcester — A Wilson Atwood, Worcester
 Worcester North — Donald B Cheetham, Athol

OFFICERS OF THE SECTIONS FOR 1949-1950**Psychiatry and Neurology**

Chairman, Walter E Barton, Dorchester, *secretary*,
 Augustus S Rose, Belmont

Ophthalmology and Otolaryngology

Chairman, James J Regan, South Boston, *secretary*,
 Lawrence R Dame, Greenfield

Industrial Health

Chairman, Daniel L Lynch, Roslindale, *secretary*,
 Albert O Seeler, Waban

CASE 35301

PRESENTATION OF CASE

A seventy-five-year-old housewife entered the hospital with intermittent frequency, burning and hematuria.

Fourteen years before entry and again seven years later, she underwent suprapubic operations for carcinoma of the bladder, following which she was entirely well until two months before entry, when the above-mentioned symptoms developed.

Physical examination revealed a blood pressure of 110 systolic, 90 diastolic, and moderate cardiac enlargement, with a very slight, soft, apical, sys-

tolic murmur. Pelvic examination showed no fixation of the bladder base and no induration.

Examination of the blood disclosed a red-cell count of 3,160,000, with a hemoglobin of 9.7 gm, and a white-cell count of 9000. The nonprotein nitrogen was 28 mg per 100 cc. The urine had a specific gravity of 1.014 and gave a ++ test for albumin; the sediment contained an occasional white cell, rare red cells and many bacteria. A blood Hinton test was negative.

An intravenous pyelogram showed normal-appearing urinary passages on the right. There was no evidence of excretion on the left over a period of one hour. Both kidney shadows were normal in size, shape and position. The bladder shadow demonstrated lobulated filling defects of the floor and left side. The bones were slightly decalcified, but no localized areas of destruction were seen. There was a group of calcifications in the left side of the pelvis (Fig 1).

On cystoscopy two small papillary tumors of the bladder base and a questionable infiltrating tumor involving the anterior wall just above the vesical orifice were seen. Biopsies of the right and left base and the anterior wall showed no tumor. Retrograde pycelography was reported as demonstrating a small amount of filling on the left, which outlined dilated calyces with irregular margins and a large, round defect in the pelvis of the kidney. The ureter was widened and tortuous, and irregular defects were present within it. A urine culture, taken at the time of cystoscopy, grew abundant colon bacilli and nonhemolytic streptococci.

On the twelfth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR SYLVESTER B KELLEY As one glances through the history of this seventy-five-year-old woman there are a number of preliminary thoughts that run through one's mind in an attempt to find an explanation for the symptoms presented. One surmises that with a red-cell count of 3,160,000 and a hemoglobin of 9.7 gm the disease had been going on much longer than the two-month period described by the patient. Recurrent cancer in the bladder is a good possibility, freedom from symp-

FIGURE 1

toms for seven years after specific therapy for a bladder tumor is by no means indicative of a cure. The normal nonprotein nitrogen and the reasonably good specific gravity of the urine suggest that one kidney at least had fairly good function. It is unfortunate that the physical examination includes no mention of the kidneys or abdominal findings. In the majority of cases a tumor of the renal parenchyma can be felt by bimanual palpation. Similarly, another x-ray film taken twenty-four hours after the injection of the intravenous dye might have given invaluable assistance in revealing why the left kidney failed to excrete enough dye for visualization of the pelvis and calyces within the customary hour. The lobulated filling defects on the floor and left side of the bladder should be interpreted cautiously. Extravesical masses, or even an enlarged prostate in male patients, may simulate

bladder tumors. Cystoscopic biopsies are not infallible. The operator may get his specimen from the area around a tumor, or the tissue that he removes may vary greatly in its degree of malignancy from that elsewhere in the same tumor. Whatever this patient had, it apparently involved the kidney, ureter and bladder.

A history of burning, frequency and hematuria ordinarily suggests stone, tumor, tuberculosis or inflammatory reaction somewhere along the urinary tract.

First, let us consider an acute inflammatory process, not because it is the most likely but because it can be eliminated most easily. Such a condition would have caused more severe symptoms and would have been constant. The urine, furthermore, would have contained more pus cells. An infection of the urinary tract severe enough to cause gross hematuria would be manifested by a generalized inflammatory reaction in the bladder, which certainly would have been commented upon by the cystoscopist. I believe, then, that the patient had something more than a colon-bacillus infection of the urinary tract.

Tuberculosis has no respect for age, but it is distinctly less common in the urinary tracts of elderly people than in those of patients between twenty and thirty-five. Although the dilated calyces with irregular margins are consistent with renal tuberculosis, this disease should not have caused a filling defect of the renal pelvis. This degree of tuberculous involvement of a kidney, furthermore, would have been accompanied by the characteristic retraction of the ureter and gaping ureteral orifice as noted by cystoscopy. Let us eliminate tuberculosis, therefore, from the possibilities.

Calculous disease of the urinary tract merits consideration, but is a rather unlikely cause of these symptoms. The patient mentioned no pain in the side, and no calculi are mentioned in the x-ray report. A nonopaque uric acid stone in the kidney pelvis might account for the filling defect in the left kidney, but a stone there would probably have caused a more extensive generalized dilatation of the pelvis and all the calyces. A nonopaque stone blocking the lower ureter would have resulted in a uniform dilatation of the ureter above the obstruction instead of the irregular defects described in the history. In view of these considerations I believe that stones in the urinary tract do not explain the clinical picture.

This leaves cancer as the final possibility. Despite the negative biopsies I believe the patient had carcinomatous areas in her bladder. At times, I will grant that an indwelling urethral catheter chafing against the bladder mucosa may create lesions resembling bladder tumors, but here we have no mention of previous constant drainage and so I believe that we should lend credence to the views of the cystoscopist. Even in the presence of smooth, regular outlines of the kidneys, tumors of the renal

parenchyma are possible. Without the characteristic narrowing and elongation of the calyces, however, this type of renal tumor is unlikely. The generalized dilatation of the calyces and the defect in the outline of the renal pelvis are more consistent with the papillary type of carcinoma involving the kidney pelvis primarily. The tendency of these papillary tumors to metastasize down the ureter also would explain the dilatation and irregular filling defects of the ureter on the basis of secondary implants from the pelvis. Primary tumor of the ureter can produce similar filling defects, but this is a relatively uncommon disease and it probably would not be accompanied by filling defects of the kidney pelvis about it. In cases of long standing, tumors of the renal pelvis may even extend down the ureter and cause implants in the bladder mucosa. In my opinion, therefore, the history and x-ray findings in this case could all be explained satisfactorily by a papillary carcinoma of the left renal pelvis with secondary implants in the left ureter and in the bladder.

May we see the x-ray films?

DR STANLEY M WYMAN: The first three films are after intravenous examination and are normal. At the end of sixty minutes the left kidney does not appear to be appreciably larger than it was at the beginning of the examination. This suggests that the kidney is not functioning. The areas of calcification described lie in the pelvis above the bladder, slightly to the left, and I would say outside the urinary passages. The filling defect in the bladder can be seen best on the empty film. There is a large, irregular, filling defect on the left, and there is a suggestion of smaller defects about it. The last film is a retrograde examination. We have only one film, and it shows a large number of irregular, nonopaque, filling defects involving the upper third of the ureter and pelvis. The calyces seem to be wide and irregular.

DR KELLEY: This dilated lobular ureter is not quite what I had expected from the description, but I think it fairly well eliminates the possibility of tuberculosis and nonopaque stone. It looks as if something were growing from the lining of the renal pelvis out toward the calyces. Sometimes blood clots give this irregular filling of the ureter.

After viewing these x-ray films I will still adhere to my original guess of a papillary tumor primary in the renal pelvis, with secondary implants in the ureter and bladder.

DR WYLAND F LEADBETTER: I have nothing to add except that the procedures were carried out as indicated. We exposed the kidney through a left lumbar incision and found a very dilated, looped ureter, which seemed to contain tumor. The ureter was ligated just above the pelvic brim and resected with the kidney. Then through an anterior approach an extraperitoneal resection of the lower ureter with a small cone of bladder was carried out

CLINICAL DIAGNOSIS

Papillary carcinoma of left ureter, renal pelvis and bladder

DR KELLEY'S DIAGNOSIS

Papillary carcinoma of left ureter, renal pelvis and bladder

ANATOMICAL DIAGNOSES

Papillary carcinoma of renal pelvis, with extension into ureter and with metastases to ureteral mucosa

Hydronephrosis

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: As this photograph (Fig 2) shows, there is a large papillary friable tumor

FIGURE 2

involving the entire pelvis and extending into the proximal ureter. It is also evident that there are numerous mucosal metastases not only in the upper

ureter but also in the lower portion removed separately (Fig 2) Microscopically the tumor is fairly well differentiated and might be graded two (on a scale of three)

About a month later a cystoscopy showed a papillary tumor about 3.5 cm in diameter with a broad base occupying the left posterior wall behind the left ureteral region. This was resected transurethrally, and radon seeds implanted. Histologically the tumor was similar to that in the kidney and ureter. On a routine cystoscopic checkup six months later three more small papillary tumors were seen in this same region of the old ureteral orifice, which had been excised at the first operation. In addition there were now several others on the anterior and lateral walls. All these tumors were thoroughly coagulated. It was believed that cystectomy was not indicated because of the patient's age.

The question whether these tumors implant or are independent growths always arises in such a case. I personally have leaned toward the idea that many of the so-called metastases or recurrences were really new tumors produced by the same stimulus that caused the original one. In this case, however, the evidence seemed to be more in favor of implantation or recurrence.

CASE 35302

PRESENTATION OF CASE

First admission A sixty-five-year-old man entered the hospital with signs of intestinal obstruction and abdominal pain of six days' duration. A barium enema showed a filling defect in the descending colon. On the fifth hospital day a cecostomy was performed, and on the eighteenth day a freely movable segment of descending colon containing an adenocarcinoma (Grade III) was excised and an end-to-end anastomosis made between the severed ends of bowel. The tumor had penetrated the overlying serosa and extended to several regional lymph nodes. All these nodes were removed, and no distant metastases were found. The gall bladder was distended, tense and full of stones. The postoperative course was stormy. Wound sepsis developed, and when this was controlled and the cecostomy tube removed, an abscess developed under the left leaf of the diaphragm, which proved to be connected by a fistulous tract to the bowel anastomosis. A transverse colostomy was performed, and the abscess drained. Large doses of penicillin and a short course of sulfadiazine were used in conjunction with six whole-blood transfusions and one plasma transfusion during this long illness. Later, the wound had to be reopened, and another abscess in the same region was entered and drained. The patient then began to complain of calf pain, and his left leg was swollen. Bilateral ligation of the superficial femoral

veins was done. He was discharged on the sixty-fifth day after admission.

Final admission (thirteen days later) After discharge the patient felt well and was ambulatory. He increased his activities, had a good appetite and gained weight. On the day before readmission he had a sudden, severe shaking chill, following which his temperature was found to be 101°F. He complained of pain in the left chest, and had a slight cough productive of small amounts of white sputum. Later in the day there were more chills, and the patient became confused and disoriented. He was brought to the hospital thirty-six hours after the first chill.

Physical examination revealed a disoriented man. The skin was hot and dry. The scleras were icteric. The right pupil was smaller than the left, and both reacted sluggishly. The tongue was red and coated. The heart was enlarged to percussion. A Grade II systolic murmur and a diastolic gallop were heard at the apex. The percussion note over the left-lung base was dull, and the breath sounds distant. No bronchial breathing or rales were heard. The drainage wound in the left flank was healed. The colostomy site was clean. The abdomen was soft except in the right upper quadrant, where there were resistance and tenderness. Neurologic examination was negative.

The temperature was 102°F, the pulse 100, and the respirations 28. The blood pressure was 115 systolic, 60 diastolic.

Examination of the blood showed a hemoglobin of 13.7 gm per 100 cc and a white-cell count of 10,550, with 87 per cent neutrophils. The specific gravity of the urine was 1.016, and there was a ++ test for albumin and a + foam test for bile. The sediment was loaded with hyaline casts. Examination of the spinal fluid was negative. A chest film was normal. Further studies on the day after admission elicited the following information: a serum bilirubin of 2.6 mg per 100 cc direct, 3.5 mg indirect, a chloride of 88 milliequiv per liter, a carbon dioxide of 23.2 milliequiv per liter, an amylase of 38 units per 100 cc, a nonprotein nitrogen of 60 mg per 100 cc, and a total protein of 6.3 gm per 100 cc. A throat culture was negative for beta-hemolytic streptococci and pneumococci.

Thirty-six hundred units of penicillin was given intramuscularly every two hours. The night after admission the patient was comatose. Respirations were deep at 20 per minute. The temperature had fallen in a steady line to 95°F. The bladder was catheterized, but no urine was obtained. Review of the blood smear in hematologic consultation revealed no toxic granules in the neutrophils in a nearly normal count, the presence of "viral lymphocytes" was noted. Death occurred on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR VICTOR G BALBONI This sixty-five-year-old patient was first admitted to the hospital with signs of intestinal obstruction that was found to be due to cancer of the descending colon. This cancer, as well as several locally involved lymph nodes, was removed, and no distant metastases were found at the time of operation. It was noted at operation that he had cholelithiasis. The postoperative course was complicated by the development of a left subdiaphragmatic abscess, which required drainage. Presumably at the time of the operation he was transfused, and he was transfused several times again during the first hospital admission, which was a long one amounting to sixty-five days. Sometime during this first hospital admission he developed a thrombophlebitis of the left leg, and both superficial femoral veins were tied off. There was no evidence of pulmonary embolism during the first admission.

He went home, and was up and about, apparently eating well and having no symptoms, when he suddenly became acutely ill with chills, fever and pain in his chest requiring readmission to the hospital.

This episode raises the question of whether or not he could have had a pulmonary embolus. However, there was no hemoptysis, no rales were heard in the lungs, and his rapidly downhill course, with the development of jaundice and renal failure, does not suggest pulmonary embolism. Jaundice may occur with large pulmonary infarcts, but the jaundice is usually mild and does not develop for several days after the infarction. The jaundice in these cases is presumably due to the breakdown of blood in the infarcted area of the lung and almost always occurs in a patient with congestive heart failure. Clinical examination of the chest on this second entry revealed some dullness and diminished breath sounds in the left lower lung posteriorly, but these findings could be well accounted for by a high diaphragm resulting from his previous subdiaphragmatic abscess. Pulmonary embolism after both superficial femoral veins had been ligated would also be unusual. Emboli can develop proximal to the ligation of the superficial femoral veins or in the deep femoral veins, but such a course of events seems unlikely in this case.

We know that this man had cholelithiasis discovered at the time of operation, and the possibility of acute cholecystitis with obstruction of the common bile duct must be considered. The serum bilirubin was 2.6 mg per 100 cc direct and 3.5 mg indirect. In obstructive jaundice the van den Bergh reaction is primarily of the direct type, thus these readings although not very helpful suggest that the reaction was primarily indirect, indicating that the jaundice was of the type seen in primary liver-cell damage. No other liver-function tests are given. It would have been helpful if we had had a thymol

turbidity test and an alkaline phosphatase. In obstructive jaundice the alkaline phosphatase is usually elevated above the normal of 5 Bodansky units. In obstructive jaundice the thymol turbidity is usually normal (0 to 4 units), and in hepatocellular jaundice (hepatitis) the thymol turbidity is usually markedly elevated anywhere up to 30 or 35 units but rarely above 20 units. The serum amylase remains normal in both types as it was in this case.

The patient's course on the second hospital entry was rapidly downhill, with the development of jaundice, coma and renal failure.

On the basis of the evidence I must assume that the jaundice was of the intrahepatic type seen when the liver is severely damaged. Miliary metastases to the liver from the original carcinoma of the colon could produce this picture, as also could multiple metastatic abscesses of the liver. I see no way of completely ruling out these possibilities. The white-cell count was not very abnormal being only 10,500, with 87 per cent neutrophils, and is against pyogenic abscesses of the liver. If there were multiple metastases in the liver, it is reasonable to assume that they would have been recognized at the time of the operation.

None of the diagnoses so far mentioned seem to explain adequately the rapidly downhill course that this patient showed, with clinical evidence of hepatic and renal failure. With severe hepatic failure coma is quite common, and renal failure may occur. The exact cause of the renal failure in severe liver disease is not clearly understood, but it is known that a type of nephrosis may develop. We know that this man had a transfusion at the time of his operation for cancer of the bowel, seventy-eight days prior to the development of the jaundice and that he had several other transfusions during his first hospital stay. Hepatitis of the so-called homologous serum or transfusion type may develop anywhere from thirty to a hundred and twenty days after transfusion, most cases occurring between the fiftieth and the ninetieth day.¹ The hepatitis following transfusions is pathologically indistinguishable from the hepatitis that is epidemic going under the term of epidemic infectious hepatitis. The evidence to date indicates that both types of hepatitis are due to viruses and that the virus of post-transfusion hepatitis is different from that causing epidemic hepatitis. In both types it is common to have a polymorphonuclear leukopenia in the peripheral blood and varying numbers of mononuclear cells not unlike those seen in infectious mononucleosis. This patient did show some of these "viral lymphocytes" in the peripheral blood. Either type of hepatitis may be mild, or may be severe and fulminating, with death ensuing within three or four days as in this case. At autopsy these cases show massive central necrosis of the liver lobules such

as that described by Dr Mallory,¹ and that is what I believe this case will show

CLINICAL DIAGNOSIS

Homologous serum jaundice

DR BALBONI'S DIAGNOSES

Hepatitis, transfusion type, with hepatorenal failure
Cholelithiasis
Partial colectomy
Multiple abscesses of liver?
Carcinomatosis of liver?

ANATOMICAL DIAGNOSES

Viral hepatitis, fulminant, homologous serum type
Arteriosclerosis, marked, aortic and coronary
Coronary thrombosis, old
Pulmonary embolism, left lower lobe
Cholelithiasis
Operative wounds resection of carcinoma of colon, colostomy, drainage of subdiaphragmatic abscess, ligation, bilateral, of superficial femoral veins

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Dr Balboni was correct in predicting that this patient would show evidence of hepatitis at autopsy. The liver looked grossly exactly like the ones we saw during the war and which Lucké and I² described as the fulminant form of hepatitis. The organ was only moderately shrunk and on section looked like an extremely severe nutmeg liver, with hemorrhagic and depressed lobular centers and pale, raised portal areas. Microscopically, the liver cells had almost completely disappeared, and the periportal tissues were densely infiltrated with mononuclear cells. It is not unusual for death to occur so rapidly that there is not time for much jaundice to develop. Profound coma is very characteristic and, when it develops before jaundice is apparent, may lead to suspicion

of various forms of intracranial disease. I remember a case in which a craniotomy was performed under the impression that the patient suffered from a subdural hematoma.

As Dr Balboni has already pointed out the pathological lesion of homologous serum jaundice is indistinguishable from that of epidemic hepatitis. There is no certain way to distinguish the two diseases except by the inoculation of human volunteers. The epidemic strain will infect when fed by mouth and can be demonstrated in the intestinal content. When the virus is given transcutaneously the incubation period is only two to three weeks as against the two to six months for the serum-jaundice strain. This patient developed jaundice some seventy days after his operation and transfusion therapy, so the incubation period was correct for serum jaundice and we may be reasonably confident of the diagnosis.

The remainder of the autopsy showed numerous lesions but none that seemed to bear upon his death. He had severe coronary sclerosis and one point of occlusion in the descending branch of the left coronary artery, but no evidence of infarction. A small pulmonary embolus was found in the left lower lobe. A stone was still present in the gall bladder but was causing no trouble. A few scars of old traumatic brain injury were present in the meninges, raising some suspicions that he might one time have been a prize fighter, but no acute lesion other than slight edema was found to account for his profound coma. This is usual in hepatitis. There was no evidence of metastasis or recurrence of the carcinoma, but the large bowel contained many polyps, at least one of which showed malignant cytology though no evidence of invasion. It seems probable therefore that further cancers of the bowel would have developed sooner or later.

LAW AND THE LABORATORY

THE Commonwealth of Massachusetts, in 1877, established by state law the medical-examiner system to replace the gross inefficiency and corruption of the coroner system. For the first time in the history of the country a sovereign state recognized that a physician is better qualified than a layman to investigate sudden and violent deaths.

In seventy-two years of operation the Massachusetts medical-examiner system has slowly become the prototype for reform in other states and regional jurisdictions. In 1918 the five boroughs of New York City were placed under a chief medical examiner and his assistants, with responsibility for the investigation of medicolegal deaths in a population of seven million. In 1927 Essex County (Newark), New Jersey, followed suit. New Hampshire in 1903, Maine, in 1917, Rhode Island and

Maryland, in 1939, and Virginia, in 1947, replaced the lay coroner with the physician medical examiner. Maryland improved upon the system by the establishment of a central state laboratory with a chief medical examiner and regional medical examiners. Virginia followed with a similar plan, and this year Rhode Island has added a central laboratory and chief medical examiner.

Massachusetts has not been indifferent to the need for a central laboratory and expert technical staff for medicolegal investigation. For many years the pathologist medical examiners of Suffolk County served as consultants to the nonpathologist medical examiners of the other Massachusetts counties. Occasionally in the past, sometimes unhappily, a self-styled expert testified for the prosecution. One memorable murder trial brought forth the startling admission by such an expert that he had performed the wrong test for cyanide and had subsequently lost the victim's stomach and contents.

As the Massachusetts Department of Public Safety developed through the years expert facilities in ballistics, toxicology and trace laboratories were made available to the medical examiners, police and district attorneys of the State. Since 1940 a central consultation service for medicolegal autopsies has also been provided by the Department of Public Safety through the gratuitous services of the staff of the Department of Legal Medicine of Harvard Medical School. In ten years of activity, the highly trained medicolegal pathologists of that department have performed over 1400 autopsies at the request of medical examiners and district attorneys. Hundreds of thousands of miles have been traveled to every corner of the State without charge to the Commonwealth for professional services. In addition to this overwhelming contribution of time and skill to public service, the central medicolegal laboratory has given periodic formal instruction to state and city police officers of Massachusetts and other states concerning the preservation and interpretation of evidence related to violent deaths. Constant research has been carried on to clarify the mechanisms of sudden and violent death and thus to benefit the living.

An extraordinary degree of efficiency has resulted from this close interrelation of the pathologist,

toxicologist and ballistic and trace experts. The state-police investigators working with the district attorneys listen with confidence to the pathologist from the central laboratory, who has both experience and unlimited technical assistance at his call. The combination of state-police detective free from regional prejudice and expert forensic pathologist serving without fee does much to make Massachusetts safe for the innocent and perilous for the guilty.

THE FARNSWORTH SURGICAL BUILDING

MEDICAL activity on Bennet Street in the South End has been evolving for a century and a half. The evolution has been parallel to that of similar activities in other parts of the nation. The motivation has been the same: an interest in the care of the sick, in the training of those who profess to give that care, in the growth of the knowledge upon which the treatment of the sick is based and the prevention of sickness may be accomplished, and finally in the extension of the region served far beyond the Towne of Boston and out toward the borders of New England.

On May 26 another unit was opened with appropriate exercises and an opportunity for public inspection of the Farnsworth Surgical Building. At the corner of Bennet Street and Harrison Avenue, it will provide complete surgical equipment with 165 beds. The corridors are continuous with those of the Joseph H. Pratt Diagnostic Hospital and connect directly with the Ziskind Research Laboratories. Across Bennet Street is the Boston Dispensary, which connects directly with the Boston Floating Hospital. Diagonally across Harrison Avenue is the building now being remodeled for Tufts College Medical School.

This new building embodies many modern architectural features. Its five operating rooms, located in the basement and placed radially about the central servicing facilities, are entered only by those directly concerned with the work at hand, visitors being diverted to observation domes above. They may talk with the operating personnel, however, through a two-way intercommunication system. The observation domes are placed radially about the Stearns Auditorium (in honor of Dr. A. Warren

Stearns, Jr.), thus facilitating a combination of didactic and clinical teaching. They open from the main lobby of the building. In this way patients, students and operating personnel are provided with separate areas. In the well furnished rooms much may be found that is dear to the heart of hospital superintendents.

The dedicatory program included addresses by Dr. Edward D. Churchill, chief of the General Surgical Services of the Massachusetts General Hospital, and Chester I. Barnard, president of the Rockefeller Foundation and General Education Board. After the exercises tea was served, and there was a pleasant opportunity for leisurely inspection of the premises. The *Journal* salutes this new surgical unit of the New England Center Hospital.

MULTIPLE-SCLEROSIS SURVEY

ORGANIZATION and co-operative effort are providing expanded opportunities for both the study of disease and public education in health and sickness. One of the most recent of these collaborative case-finding ventures following hard upon those that have been conducted in the attack on tuberculosis, cancer, diabetes and heart disease is the current epidemiologic survey of multiple sclerosis.

Locally, the multiple-sclerosis survey in Boston and Brookline, in which the co-operation of all physicians is sought, is being conducted by the Department of Epidemiology of the Harvard School of Public Health. Aiding in the study are the Hospital Council of Boston, the Committee on Public Health of the Massachusetts Medical Society and the local district medical societies. Other regional studies being sponsored by the National Multiple Sclerosis Society and activated by grants-in-aid are either in progress or planned for the near future in New Orleans, San Francisco, Denver and Winnipeg. All will be conducted in co-operation with local schools of medicine or public health.

The purpose of the multiple-sclerosis survey, according to a release from the Harvard School of Public Health, is to determine the prevalence and distribution of the disease and to evaluate apparent differences in morbidity and mortality related to geography, climate, race and other factors. All

physicians in the areas designated are being requested, by individual letter, to provide information on appropriate forms on patients with multiple sclerosis seen within the past five years. The data will be used only for statistical purposes.

A young girl, near Philadelphia, laboring under some form of lunacy, by pretending to hold conversation with the Lord, is stirring up all the crazy people in the region, who flock in crowds to see one more possessed than themselves
Boston M & S J., July 25, 1849

MASSACHUSETTS MEDICAL SOCIETY

NORFOLK DISTRICT WOMAN'S AUXILIARY

The following officers for 1949-1950 were recently elected by the Woman's Auxiliary of the Norfolk District Medical Society: president, Mrs. John B. Hall, president-elect, Mrs. Joseph L. Tansey, vice-president, Mrs. David L. Lionberger, treasurer, Mrs. Benjamin Sachs, recording secretary, Mrs. Elliott Bresnick, and corresponding secretary, Mrs. David L. Halbersleben. The Advisory Council consists of Mrs. John W. Spellman, Mrs. Edward C. Smith, Mrs. W. Richard Ohler, Mrs. James D. Hepburn, Mrs. Norman A. Welch, Mrs. Leighton F. Johnson, Mrs. George W. Papen, Mrs. C. J. E. Kickham, Mrs. George F. Wilkins, and Mrs. Carlton E. Allard. The officers of the standing committees are as follows: Membership, Mrs. Harold N. McKinney, chairman, and Mrs. H. S. Levine, co-chairman; Public Relations and Publicity, Mrs. George F. Wilkins, chairman; Legislative, Mrs. Solomon L. Skvirsky, chairman; Ways and Means, Mrs. Goodwin A. Johnson, chairman, and Mrs. Newton C. Browder, co-chairman; Entertainment and Program, Mrs. John W. Spellman, chairman, and Mrs. Joseph L. Tansey, co-chairman; Hospitality, Mrs. Samuel Nadel, chairman, and Mrs. Arthur L. Gaetani, co-chairman; and Time and Place, Mrs. George W. Papen, chairman, and Mrs. Edward C. Smith, co-chairman. The historian is Mrs. Fedele M. Failace.

DEATHS

HULL — Ira B. Hull, M.D., of Gloucester, died on July 9. He was in his sixty-seventh year.
Dr. Hull received his degree from Harvard Medical School in 1912.
His widow survives.

PARKER — Ernest L. Parker, M.D., of Cohasset, died on January 18. He was in his seventy-first year.
Dr. Parker received his degree from Harvard Medical School in 1894.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

CARON — Damase Caron, M.D., of Manchester, died on June 9. He was in his seventy-fourth year.
Dr. Caron received his degree from University of Montreal Faculty of Medicine in 1900.
His widow, three daughters, three sons, eight grandchildren and two brothers survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

TETANUS TOXOID AVAILABLE FROM BIOLOGIC LABORATORIES

The Division of Biologic Laboratories of the Massachusetts Department of Public Health has received a license from the National Institutes of Health to produce and distribute tetanus toxoid, fluid.

The value of tetanus toxoid immunization was amply shown during World War II. In civil life it is especially useful to protect persons whose occupations expose them to the danger of cuts, burns or abrasions contaminated with dirt. The toxoid eliminates the necessity of repeated prophylactic doses of tetanus antitoxin, a horse-serum product, to such persons.

The toxoid is available in packages containing three 1-cc vials, for immunizing one person, and in large 20-cc vials for clinic use. The package containing three 1-cc vials may be obtained from biologic distribution stations or by direct request to the Biologic Laboratories, 375 South St., Jamaica Plain, 30, Massachusetts. The 20-cc vials will not be stored by the biologic distribution stations and should be obtained directly from the Division of Biologic Laboratories.

COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JUNE, 1949

DISEASE	RÉSUMÉ		
	JUNE 1949	JUNE 1948	SEVEN YEAR MEDIAN
Chancroid	4	0	1*
Chicken pox	1978	1665	1400

*Five year median

COMMENT

Diseases above the seven-year median were chicken pox, diphtheria, dog bite, German measles, Pfeiffer-bacillus meningitis, pneumococcal meningitis and poliomyelitis.

Diseases below the seven-year median were measles, meningococcal meningitis and scarlet fever.

Chicken pox was at the highest level ever recorded in June.

Diphtheria still remains unusually prevalent for this season. German measles is still high for the season although the prevalence is less than half that of the previous month.

The incidence of poliomyelitis for the month of June was the highest since the disease has been reportable, however, the cases still remain scattered, with some concentration in Milton and Lynn.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Belmont, 1, Boston, 34, Brookline, 1, Cambridge, 1, Medfield, 1, New Bedford, 1, Salisbury, 1, total, 40.

Dysentery, bacillary, was reported from Waltham, 1, total, 1.

Infectious hepatitis was reported from Haverhill, 1, Waltham, 2, total, 3.

Malaria was reported from Newton, 1, total, 1.

Meningitis, meningococcal, was reported from Cambridge, 1, Hingham, 1, Holden, 1, Lynn, 1, Springfield, 1, Watertown, 1, total, 6.

Meningitis, Pfeiffer-bacillus, was reported from Lawrence, 1, Lowell, 2, Pittsfield, 1, Stoneham, 1, Stow, 1, Wellesley, 1, Worcester, 1, total, 8.

Meningitis, pneumococcal, was reported from Boston, 1, Cambridge, 1, Lynn, 2, Wakefield, 1, total, 5.

Meningitis, streptococcal, was reported from Brockton, 1, total, 1.

Meningitis, undetermined, was reported from Framingham, 1, Grafton, 1, total, 2.

Poliomyelitis was reported from Boston, 3, Brookline, 1, Cambridge, 1, Canton, 1, Dennis, 1, Everett, 1, Haverhill, 1, Hudson, 1, Lawrence, 1, Leominster, 1, Lynn, 6, Milton, 5, Newburyport, 2, Somerville, 1, Waltham, 1, Watertown, 1, Worcester, 1, total, 29.

Salmonellosis was reported from Boston, 2, Braintree, 1, Brookline, 1, Worcester, 1, total, 5.

Septic sore throat was reported from Boston, 4, Cambridge, 1, Medford, 1, Newburyport, 1, Quincy, 1, total, 8.

Tetanus was reported from Wakefield, 1, Whitman, 1, total, 2.

Trichinosis was reported from Boston, 1, Salem, 1, total, 2.

Typhoid fever was reported from Peabody, 1, Plymouth, 1, total, 2.

Undulant fever was reported from Danvers, 1, Lunenburg, 1, total, 2.

MISCELLANY

AMERICAN COLLEGE OF CHEST PHYSICIANS

Dr Dwight E. Harken, of Boston, presented a paper on "Experiences in Cardiac Valve Surgery" at the fifteenth annual meeting of the American College of Chest Physicians, held in Atlantic City, New Jersey, June 2-5.

Dr Richard H. Sweet, also of Boston, presented a paper entitled "Recent Advances in Esophageal Surgery."

The following physicians from the New England states received fellowship certificates at the Convocation held at the Ambassador Hotel, Atlantic City, on June 4: Dr Maxwell J. Antell, of Bridgeport, Connecticut; Dr Francis D. T. Bowen, of Newington, Connecticut; Dr Arthur H. Chernoff, of Saugus, Massachusetts; Dr Gisela K. Davidson, of Portland, Maine; Dr Francis E. O'Brien, of Haydenville, Massachusetts; and Dr Arthur D. Ward, of Worcester, Massachusetts.

BOOKS RECEIVED

The receipt of the following books is acknowledged and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Technik der kinderärztlichen Differentialdiagnostik für Studierende und praktische Ärzte. By Prof. Dr. Alphons Solch, chief of the Karolinen-Kinderspitale der Stadt Wien. 8° cloth, 384 pp., with 22 tables. Basel: Benno Schwabe & Co., 1948. Gebunden Fr. 20.

This textbook on the technic of the differential diagnosis of children's diseases is divided into three parts: general principles of diagnosis, differential diagnosis by symptoms, and regions and organs. The volume is well published and should prove valuable to German-reading physicians interested in pediatrics.

The Practice of Endocrinology. Edited by Raymond Greene, M.A., D.M., M.R.C.P. 8° cloth, 366 pp., with 53 illustrations and 91 figures. London: Eyre and Spottiswoode (Publishers), Limited, 1948. 52s. 6d. The Practitioner Textbooks.

This composite textbook is the joint work of seven specialists and covers the whole field of endocrinology. The text was completed in the spring of 1946, but its publication was delayed because of printing difficulties. An insert reviews some of the important literature of 1947. The material is well arranged. There is a comprehensive index, and the type, printing and paper are excellent. The volume, which weighs 2½ pounds and is easy to handle, is a concrete example of the possibility of using a soft light paper for large volumes. The work represents the British point of view but should be in all medical libraries and in all collections on the subject.

An Introduction to Gastro-Enterology. By Walter C. Alvarez, M.D., professor of medicine, University of Minnesota, Mayo Foundation, and senior consultant, Division of Medicine, Mayo Clinic. Fourth edition, revised and enlarged. 4° cloth, 903 pp., with 269 illustrations. New York: Paul B. Hoeber, Incorporated, 1948. \$12.50.

This fourth edition of a standard treatise has been thoroughly revised. Over 400 articles and books appearing since the third edition (1940) have been noted throughout the text. Much material has been added in the chapters on the pylorus, the nerves running to the bowel and to the gall bladder, the functions of the colon, flatulence, the electro-enterogram, technical methods and apparatus, and vagotomy in man. The text is concluded with a comprehensive bibliography of about 2800 titles. There is a good index. The type and printing are excellent. The volume weighs over 5 pounds and is not easy to handle. The relatively few illustrations do not justify the use of a heavy coated paper. The book should be in all medical libraries and in all collections on the subject.

Technic of Medication. By Austin Smith, M.D., C.M., M.Sc., director, Division of Therapy and Research, and secretary, Council on Pharmacy and Chemistry, American Medical Association. 12° cloth, 255 pp. Philadelphia: J. B. Lippincott Company, 1948. \$4.00.

This volume is the successor to the *General Technic of Medication*, written by Dr. Bernard Fantus, and first published in 1926 and last in 1938. The present work retains some of the old material rewritten, and much new material has been included. The work is intended primarily for the medical student and intern but should prove useful to the general practitioner. It includes chapters on the prescription and on oral, parenteral, rectal and genitourinary administrations, and dermal and mucous-membrane applications. The book is well published and forms part of the *Lippincott Essentials Series*.

Diabetic Manual for the Doctor and Patient By Elliott P Joslin, M.D., Sc.D., medical director, George F Baker Clinic, New England Deaconess Hospital, and consulting physician, Boston City Hospital Eighth edition 12", cloth, 260 pp., with 51 figures and 24 tables Philadelphia Lea and Febiger, 1948 \$2.50

This standard manual has been fully revised and brought up to date. Emphasis is placed on new discoveries, such as the modification of protamine zinc insulin, making possible in many cases one injection instead of two as formerly required, the significance of uric acid diabetes, and the new avenues of experimentation that opens up a possible prevention of diabetes among relatives. The statistics presented by Dr Joslin are remarkable. In cases seen up to 1914 only 1 patient in 55 had lived over twenty years with the disease, but in the period 1944 to 1948 the number had increased to 1 in 4—a truly remarkable achievement. In 2659 children treated since 1938, 2235 were alive at the time of writing. The book is recommended for all public libraries and should be available to all diabetic patients and their families. The price is moderate and within their means.

Factors Regulating Blood Pressure Transactions of the second conference, January 8-9, 1948, New York Edited by B W Zweifach and Ephraim Sborr, Department of Medicine, Cornell University Medical College 8", paper, 170 pp New York Josiah Macy, Jr Foundation, 1948 \$2.75

This conference was participated in by 23 authorities from the United States and Canada. Ten of them presented papers for discussion on varying aspects of the subject. The book should be in all medical libraries and in the collections of physiologists and physicians interested in blood pressure.

District Nursing A handbook for district nurses and for all concerned in the administration of a district nursing service By Eleanor J. Merry, S.R.N., S.C.M., C.S.P., H.V. Cert of R.S.I., social studies cert., Bedford College, education officer, Queen's Institute of District Nursing, and examiner for the Royal Sanitary Institute, and Iris D. Irven, S.R.N., S.C.M., H.V. Cert of R.S.I., superintendent, Worcester City Nursing Association 12", cloth, 266 pp., with 18 figures and 16 plates Baltimore Williams and Wilkins Company, 1948 \$4.00

This small volume covers the whole field of district nursing (visiting nursing) as practiced in England. The text was printed in Great Britain. The publishing is excellent. The book forms part of *Baillière's Handbooks for Nurses*. It should be in all nursing collections.

Hematology By Cyrus C. Sturgis, M.D., professor of internal medicine and chairman of the Department of Internal Medicine, University of Michigan Medical School, and director of the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan 4", cloth, 915 pp., with 72 illustrations Springfield, Illinois Charles C. Thomas, 1948 \$12.50

This new work on hematology is based on the author's long experience supplemented by a knowledge of the literature of the subject. The material is well arranged. The author discusses in order the anemias, hemorrhagic states, the leukemias, malignant lymphoma and other special diseases of the blood. The two last chapters are on sternal puncture and blood transfusions and blood substitutes. An extensive bibliography of fifty-three pages concludes the text. There is a good index. The printing is done on a coated, filled, glaring paper, not necessary because the color plates are tipped into the volume. The volume weighs over 4 pounds, and much of the weight could have been saved by the use of another kind of paper. It is time that publishers began to think of the convenience of the reader and made their books as light as possible. The volume is recommended for all medical libraries and for all physicians interested in diseases of the blood.

Health Instruction Yearbook 1948 Compiled by Oliver E. Bird, Ed.D., M.D., F.A.P.H.A., professor of health education and director, Department of Hygiene School of Educa-

tion, Stanford University. With a foreword by Ray L. Wilbur, M.D., chancellor, Stanford University 8", cloth, 320 pp. Stanford, California Stanford University Press, 1948 \$3.50

This volume of a series inaugurated in 1943 is based upon 1514 articles read by the author, of which 321 were selected for condensation and publication. They were found in 100 different publications. It is interesting to note that nineteen selections were made from the *Congressional Record*. A bibliography of the articles follows the text. There are author and subject indexes. The book is well published and should be in all medical libraries and in all public-health collections. It affords an easy way of keeping up with the current literature on the subject.

"Hi-Ya Neighbor" By Ruth Stevens 8", cloth, 122 pp., with 34 illustrations New York Tupper and Love, Incorporated, 1947 \$2.00

Miss Stevens relates an interesting account of the "off-the-record" hours of the late President Roosevelt, spent at Warm Springs, Georgia, where he went for treatment of poliomyelitis. A number of interesting pictures of the buildings and of the President and other patients are interspersed throughout the text. There is a detailed account of his last day at Warm Springs, where he died on April 12, 1945.

Blood Clotting and Allied Problems Transactions of the first conference February 16-17, 1948, New York, New York Edited by Joseph E. Flynn, Department of Pathology, College of Physicians and Surgeons, Columbia University 8", cloth, 179 pp New York Josiah Macy, Jr Foundation, 1948 \$3.25

Sixteen authorities took part in this conference on blood clotting. There are a number of articles on protobromin and clotting time. The type and printing are excellent. The ring type of binding does not stand for durability. The volume should be in all medical libraries.

The Child in Health and Disease A textbook for students and practitioners of medicine By Clifford G. Grulee, M.D., Rusb professor of pediatrics, University of Illinois, the School of Medicine, attending pediatrician, Presbyterian Hospital, Chicago, chief editor, *American Journal of Diseases of Children*, and secretary of the American Academy of Pediatrics, and R. Cannon Eley, M.D., associate in pediatrics and communicable diseases, Harvard Medical School, chief of isolation service and visiting physician, Infants and Children's hospitals, Boston, and member of the Committee on Awards of the American Academy of Pediatrics 4", cloth, 1066 pp., illustrated Baltimore Williams and Wilkins Company, 1948 \$12.00

This comprehensive treatise on pediatrics is the joint work of 75 competent specialists. The whole field of the care and management of the child in health and disease is covered in extenso. To compress the large amount of text into one volume it was necessary to use a two-column format and a medium-sized type. Also, the use of filled paper makes the volume too heavy to handle easily—it weighs 5 pounds. A comprehensive index of sixty pages concludes the text. This new treatise should be in all medical libraries as a reference source.

Textbook of the Rheumatic Diseases Edited by W. S. C. Copeman, O.B.E., M.D., F.R.C.P., physician to the Rheumatism Department and lecturer in the Medical School, West London Hospital, physician to Arthur Stanley Institute of Rheumatic Diseases (Middlesex Hospital), Hunterian professor, R.C.S., senior physician, the Hospital of St. John and St. Elizabeth, and consultant for rheumatic diseases, Royal Hospital for Incurables, and consultant to L.C.C. 8", cloth, 612 pp., with 351 illustrations Baltimore Williams and Wilkins Company, 1948

This composite treatise is the work of 24 British authorities on rheumatic diseases. The whole field of the subject is covered, beginning with nomenclature and history and followed by the anatomy and physiology of pain and of the joints, discussions of the various rheumatic diseases,

diagnosis, pathology, radiology, chapters on the various methods of treatment, the psychiatric, social and industrial aspects and statistics. Indexes of authors and subjects conclude the book. The publishing is excellent in every way. The illustrations are particularly good, both of radiographs and plates in color. The printing was done in Great Britain. The book is recommended for all medical libraries and to all specialists on rheumatism.

Experimental Immunochemistry. By Elvin A. Kabat, Ph.D., associate professor of bacteriology, College of Physicians and Surgeons, Columbia University, and the Neurological Institute, New York City, and Manfred M. Mayer, Ph.D., associate professor of bacteriology, School of Hygiene and Public Health, Johns Hopkins University. With a foreword by Michael Heidelberger, Ph.D., professor of biochemistry, College of Physicians and Surgeons, Columbia University, and chemist to the Presbyterian Hospital, New York City. 8°, cloth, 567 pp., with 88 illustrations. Springfield, Illinois: Charles C. Thomas, 1948. \$8.75.

This book brings together the techniques employed in research in the field of immunochemistry. The emphasis has been placed on quantitative methods. For students and chemists not familiar with the subject, introductory material is provided in the early parts of the text, which is divided into four parts: immunologic and immunochemical methodology, applications and uses of quantitative immunochemical methods, chemical and physical methods and special procedures, and preparations. The printing is well done, with a good, large type on a light, nonglare paper. There is a good index. The book is an essential tool for the laboratory and should be in the reference collections of all medical libraries, and should be available to chemists and others interested in the subject.

The Renal Origin of Hypertension. By Harry Goldblatt, M.D., C.M., director, Institute for Medical Research, Cedars of Lebanon Hospital, and professor of pathology, School of Medicine, University of Southern California, Los Angeles. 8°, cloth, 127 pp. Springfield, Illinois: Charles C. Thomas, 1948. \$2.75.

In this short monograph, the author summarizes twenty years of experimental research and discusses the following problems: the production of experimental hypertension, pathologic changes in hypertensive animals, pathogenesis, the humoral mechanism, renin, hypertensinogen, hypertensin and other vasoconstrictor substances, and treatment. The importance of the subject is evidenced by its death rate. Arteriosclerotic diseases of the brain, heart and kidneys, associated with hypertension, cause about four times more deaths than cancer. The final chapter comprises a summary of the similarities and differences between human essential and experimental human hypertension. There is a good index. The volume is well published in every way. It forms part of the *American Lecture Series* and should be in all medical libraries.

The Parathyroid Glands and Metabolic Bone Disease. Selected studies. By Fuller Albright, M.D., associate professor of medicine, Harvard Medical School, physician, Massachusetts General Hospital, and consulting physician, Massachusetts Eye and Ear Infirmary, and Edward C. Reifenstein, Jr., M.D., consultant-in-charge, Department of Clinical Investigation, Sloan-Kettering Institute of Cancer Research, Memorial Hospital Cancer Center, New York City, and clinical research consultant, Ayerst, McKenna and Harrison, Limited, New York City. 8°, cloth, 393 pp., with 157 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$8.00.

The studies presented in this volume comprise in a way a summary of the work carried out on the metabolic ward of the Massachusetts General Hospital during the past twenty-four years. The articles include the normal and pathologic physiology of the parathyroid glands, clinical hypoparathyroidism and hyperparathyroidism, mode of action of vitamin D and dihydrotachysterol (A.T.10), general considerations of metabolic bone disease, osteoporosis, osteomalacia, poly-

ostotic fibrous dysplasia (*osteitis fibrosa disseminata*) and Paget's disease (*osteitis deformans*). There is a long bibliography, and author-and-subject indexes. The volume is well published and should be in all medical libraries.

The Clinical Apprentice. A guide for students of medicine. By John M. Naish, M.D. (Cantab.), M.R.C.P., and John Apley, M.D. (Lond.), M.R.C.P. With a foreword by Professor J. A. Ryle. 12°, cloth, 200 pp., with 71 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$4.50.

In this manual for interns the text is divided into two parts. The first, entitled "Examination at Leisure," discusses conditions in which there is ample time to make a complete diagnosis. The material in this part is arranged by the systems of the body, preceded by chapters of a general character. The second part, called "Examination of Acute Cases," is arranged by symptoms and considers means of establishing a provisional diagnosis on which to base immediate treatment in acute cases without undue disturbance of the patient. The symptoms singled out for discussion include the unconscious patient, the meningitic syndrome, high temperatures, acute breathlessness and convulsions. The material is well arranged, and there is a good index. The small volume is well published. The text was printed in Great Britain and naturally reflects the British point of view. The price seems excessive for such a small volume.

NOTICES

OPENINGS FOR PHYSICIANS

The Bureau of Reclamation of the Department of the Interior announces openings for two physicians at Coulee Dam, Washington, a town of 7500. Government-owned premises are for lease, in addition to which the lessee shall pay the United States for garbage disposal and refuse service, water and sewer service and electricity.

Sealed bids will be received until September 15 at 2:00 p.m. Further information may be obtained from the acting district manager of the Bureau of Reclamation at Coulee Dam.

EXAMINATIONS FOR APPOINTMENT IN NAVY MEDICAL CORPS

Examinations for the selection of candidates for appointment to the grade of lieutenant (junior grade) in the Medical Corps of the United States Navy will be conducted at all Navy Hospitals during the period September 12 to 16, 1949, inclusive.

Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the examination and who are physically and in other respects qualified, may be examined for appointment as lieutenant (junior grade) in the Medical Corps of the Navy. Candidates must be less than thirty-two years of age at the time of appointment.

Candidates will be required to appear before boards of medical examiners and supervisory examining boards at the Navy Hospital nearest their place of residence to demonstrate their physical and professional qualifications for appointment. After approval by the President of the United States and confirmation by the Senate, selected candidates will be issued appointment and orders assigning them to duty in a Navy medical facility for active service.

A lieutenant (junior grade) in the Navy Medical Corps receives pay and allowances totaling \$5011 a year if married and \$4575 50 if unmarried.

Detailed information concerning the form and procedure of application may be obtained from the offices of Naval Officer Procurement or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D.C. (Attn: Code-3424).

AUREOMYCIN THERAPY IN THE PULMONARY INVOLVEMENT OF PANCREATIC FIBROSIS (MUCOVISCIDOSIS)*

HARRY SHWACHMAN, M.D.† ALLEN C. CROCKER, M.D.,‡ GEORGE E. FOLEY,§ AND
PAUL R. PATTERSON, M.D.¶

BOSTON

THIS report is concerned with aureomycin, in the treatment of patients with pancreatic fibrosis (cystic fibrosis of the pancreas).^{1,2} Numerous advances in the understanding of the nature of the disease, development of diagnostic procedures and clinical management have been made in a series of correlated studies carried out at the Boston Children's Hospital.³⁻⁵ The common notion that this is a rare disease and that the immediate prognosis is always poor is no longer tenable. Another misconception perhaps based on historical and nosologic grounds, is the view that this is a disease solely of the pancreas and that involvement of other organs, chiefly the lungs and liver, is secondary to the disorder in the pancreas. Farber⁹ described the generalized nature of this disease and has introduced the term "mucoviscidosis" to signify the essential alteration in mucus-secreting glands as a primary defect. There is sufficient clinical variation in the disease to indicate that different degrees of involvement in different organs exist. However, one is struck by the frequency of pulmonary symptoms early in the disease in the majority of patients. These symptoms are cough, often paroxysmal and at times suggestive of pertussis or wheezing respirations with the production of thick, tenacious mucus. Atelectasis and emphysema with infection, primary or secondary, are the chief features as seen clinically and as demonstrated by roentgenograms. Indeed, the roentgenogram of

the chest may be sufficiently characteristic to suggest the diagnosis of pancreatic insufficiency.¹⁶ The respiratory rate may be increased, and the chest often becomes rounded with increased anteroposterior diameter. Vital capacity and exercise tolerance are diminished. Clubbing of the fingers and cyanosis may follow. If the pulmonary lesion advances, irreversible changes such as bronchiectasis and multiple staphylococcal abscesses may develop. A constant feature is the laboratory finding of *Staphylococcus aureus* in the nasopharynx of these patients.

The management of a patient with this disease involves consideration of replacement therapy in the form of pancreatin, the use of protein hydrolysates, the administration of a high-calorie diet with some restriction of fat, and liberal supply of vitamins including water-miscible vitamin A. The pulmonary infection is perhaps superimposed upon a more fundamental defect as yet not fully understood and its successful therapy is a problem of grave concern. The introduction of the sulfonamides, penicillin and streptomycin marked a signal advance in the management of the pulmonary infection. The use of aerosol therapy with penicillin or streptomycin, alternating with variable periods of oral sulfadiazine has become part of routine management. This combined form of therapy under constant medical supervision has proved beneficial to most patients. The cost of the therapy outlined above is high. The administration of aerosol therapy to small infants is difficult and even the older child is not always fully co-operative. The substitution of an orally effective antibiotic such as aureomycin for the expensive and more difficult form of aerosol therapy has obvious merits.

Aureomycin has been shown to have a wide range of activity against bacteria, rickettsia and certain viruses.^{2,27} It has been found to be effective in vitro against the staphylococcus species isolated from patients with pancreatic fibrosis as determined

¶A generous supply of aureomycin for use in this study was furnished by the Lederle Laboratories, New York City.

in this laboratory. A modest amount of experience in the treatment of a variety of infections in children, including some caused by the staphylococcus species, indicated that a satisfactory response could be expected and that toxic effects would be minimal. The favorable clinical response to aureomycin of a three-year-old patient with pancreatic fibrosis and extensive pulmonary involvement indicated that further use of the drug was warranted.

PLAN OF STUDY

Early in the course of this study aureomycin was used only to replace aerosol therapy with peni-

as a basis for comparison, particularly when the only change in the plan of therapy was the substitution of aureomycin for other antibiotic agent. The same dietary schedule, including the use of pancreatin, was followed. In all the cases considered in this study the diagnosis was confirmed by duodenal-fluid assay for trypsin,* and in many cases corroborated by abnormal glycine absorption after an oral gelatin feeding²⁰ and by the failure to find trypsin in the stools.²¹ A total of 35 patients have been treated and followed for at least a two-month period after the institution of aureomycin therapy. The longest period of observation extends over

cillin or streptomycin, or both. However, as experience was gained the drug was administered more liberally, even to patients with minimal pulmonary signs, who at the time were not receiving antibiotic therapy. These patients were followed in the Nu-

four and a half months. At least 15 additional patients could be included if the data were analyzed on a shorter observation period. In the latter group the response has been similar to that observed in patients followed over a longer time. Frequent laboratory observations were made, including roentgenograms of the chest, white-cell counts and nose and throat cultures, the last being taken on each visit. The patients considered ranged in age from five weeks to twelve years.

*For aureomycin, microgm per cubic centimeter; for streptomycin, mg per cubic centimeter; and for penicillin, Oxford units per cubic centimeter.

DOSAGE

Aureomycin is supplied in gelatin capsules, a form inconvenient to dispense to infants and young children. Inasmuch as the drug is unstable in solution,^{28, 29} the capsule was opened, and the dried powder given with food or drink. The drug may be rejected because of its bitter taste.† However, most parents have succeeded in its administration. At first the drug was given four times a day, but more recently it has been given in divided or even in single daily doses. An effort has been made to provide the minimal effective amount for each patient. This is roughly 20 to 30 mg per kilogram of body weight, or 125 to 250 mg daily, in divided

*In 2 patients (Cases 9 and 35) duodenal intubation was not performed. However, the diagnosis was made on clinical grounds in addition to abnormal gelatin absorption and absent stool trypsin.

†Aureomycin flavored powder (speroids) has been employed in a small number of cases with favorable results. This preparation, which can be added to milk or other fluids, overcomes the unpleasant taste.

tritional Clinic on an outpatient status or as private patients and were seen by the same observers at intervals of two to five weeks. Many of the older patients have been followed for several years in the same clinic and their response to antibiotic therapy is well known. This background served

or single doses for infants and 250 to 750 mg per day in two or three divided doses for children

BACTERIOLOGIC STUDIES

The flora of the upper respiratory tract was determined on each patient by separate nasopharyngeal and throat swabs taken before therapy and at each subsequent visit. The staphylococcus species isolated were studied for sensitivity to various antibiotics.

In vitro sensitivity to aureomycin was determined by a tube-titration method similar to that employed for penicillin sensitivity.³⁰ Aureomycin is diluted

These determinations are considered to be of only relative value, inasmuch as an arbitrary concentration of 40 microgm per cubic centimeter has been selected as an end point in this study. It should be emphasized that in no case has in vitro sensitivity influenced either the use or the dosage of the drug. Aureomycin blood and urine levels have not been undertaken in view of the difficulties inherent in such determinations.³²

Table 1 summarizes the in vitro sensitivities of the micro-organisms isolated from 32 patients other than those with pancreatic fibrosis. *Haemophilus influenzae* and *Staph aureus* were the most sensitive

†Rubeola developed 18 days after aureomycin was started
‡Rubella developed 1½ mo after aureomycin was started

so that four times the desired concentration is contained in a volume of 0.5 cc of tryptic digest broth and diluted serially by 50 per cent decrements. An eighteen-hour broth culture of the micro-organism to be tested is diluted 1:100, and 1.5 cc of this dilution is added to each 0.5-cc dose of aureomycin. The range of final concentrations usually employed is 4.0 to 0.004 microgm per cubic centimeter. The tubes are incubated at 37°C for sixteen hours. The last tube showing complete inhibition of growth is taken as the end point. Since aureomycin rapidly loses potency in solution the end points at sixteen hours may be higher than those at twelve hours. The composition of the medium also influences the rate of loss of aureomycin activity.³¹ However, with standardized conditions the method outlined above checks within one tube in duplicate titrations

of the species included in this small series. It is interesting to note that all strains of *Escherichia coli*, *Pseudomonas aeruginosa* and *Proteus vulgaris* required more than 40 microgm per cubic centimeter for inhibition, since it has been reported that aureomycin is relatively ineffective against *Ps aeruginosa* and *Pr vulgaris*.^{29, 33} The greater resistance of these species is further reflected in their appearance or persistence in the nasopharynx of patients receiving aureomycin.

RESULTS

In Vitro Studies

Table 2 presents a comparison of the in vitro aureomycin, penicillin³⁰ and streptomycin³¹ sensitivities of the strains of *Staph aureus* isolated

from the nose and throat cultures of cases of pancreatic fibrosis. Most of these patients had previously received penicillin or streptomycin, or both, but not aureomycin at the time these determinations were done. As may be seen in Table 2 only 12 per cent of the strains tested required a concentration of more than 40 microgm per cubic centimeter of aureomycin for inhibition, as compared to 44 and 74 per cent requiring more than 40 mg of streptomycin or 40 Oxford units of penicillin respectively. The number of strains resistant to penicillin and streptomycin in this series may be

on aureomycin titrations done on a single fishing from each culture. However, in other cases, multiple fishings from the same culture yielded identical sensitivities when examined in the same manner. It seems unlikely that the increased resistance observed in these 7 patients was due to variations in the sensitivity of different fishings of the same strain, as has been true of streptomycin.³⁵

Pulmonary Signs and Symptoms

The most striking effect of aureomycin therapy was the consistent amelioration of cough, dyspnea

FIGURE 1 Summary of the Effect of Aureomycin Therapy on the Course in Case 12
Note abatement of respiratory symptoms and marked weight gain

in part a reflection of previous exposure to these antibiotics. However, it has been observed in a large series of strains studied in this laboratory that *Staph aureus* is frequently penicillin resistant and streptomycin sensitive, both before and after exposure to the antibiotics.³⁵

The flora of the nose and throat was essentially unchanged in many patients after they had received aureomycin. Clinical improvement bore no relation to bacteriologic improvement, the former being commonly and the latter only rarely observed. When a staphylococcus species was isolated during the course of therapy, repeated in vitro sensitivity to aureomycin was determined. Such data were obtained on 18 patients. In 7 cases an increase in resistance ranging from fourfold to thirty-two-fold was observed. On the other hand there were only 2 cases in which repeat titrations failed to check within one tube. These observations were based

and respiratory distress. Fever, if present, was likewise favorably affected. Response was rapid, a change usually occurring within two or three days. Cough, which often kept the child awake through the night or occasionally induced vomiting, either stopped abruptly or became minimal. In some cases the parents stated that for the first time in weeks the child slept through the night without cough. This excellent response was observed in 31 of the 35 patients (Table 3). Two patients (Cases 26 and 32) showed only minimal improvement, probably because of inadequate dosage. One child (Case 35), the oldest in the series, had extensive bilateral bronchiectasis of six years' duration and a ten-day course of drug had no noticeable effect. As would be expected the physical examination of the chest showed little or no alteration in the fixed hyperexpanded thorax. Auscultatory signs varied, in some cases there was complete disap-

pearance of rales and rhonchi, and in others these signs persisted. In a few patients with bronchiectasis, clinical improvement appeared without any significant change in the physical findings in the chest.

General Condition

Improvement in disposition and well-being often accompanied the relief of respiratory symptoms. Two of the older boys felt so well that for the first time they were able to compete in the vigorous activities enjoyed by their playmates. In addition, a striking improvement in appetite was noted in many patients. This is of interest in view of the voracious appetites many of these patients possessed before pulmonary infection supervened. Weight gain was noted frequently and was striking in some patients (Fig 1).

Effect on the Stools

The action of aureomycin on the gastrointestinal tract deserves special attention. Nausea and vomiting are mentioned as frequent side effects in the adult. These symptoms were rarely encountered in this series of patients. The stools increased in number and became loose in the majority and watery in a few cases. The offensive odor commonly associated with the stools of these patients became less noticeable. The stools took on a yellowish or greenish color. There appears to be a rough relation between dosage and bowel activity. In the infant age group 500 mg or more a day may produce a troublesome diarrhea. This is likely to stop after twenty-four to forty-eight hours off the drug. In 1 patient (Case 9) the drug had to be discontinued after three separate trials, because of severe diarrhea even on minimal dosage. It should be noted that some of the most encouraging gains in weight were observed in patients who had diarrhea. In patients other than those with pancreatic fibrosis who were treated with aureomycin in the same dosage schedule diarrhea did not develop.

The effect of aureomycin on the aerobic bacterial flora of the stool has been studied in a small series of cases. The results varied from no effect in most cases to complete disappearance of the normal flora while the patient was receiving therapy. In several cases the persistence or appearance of *Ps aeruginosa* or *Pr vulgaris* was observed in the stool after the disappearance of the usual aerobic flora.

Stool Trypsin

The absence of tryptic activity in the stool is unaltered by this drug in patients receiving inadequate or no pancreatic therapy. On adequate pancreatic therapy stool trypsin is regularly demonstrated regardless of whether or not the patient is receiving aureomycin.

White-Cell Count

The white-cell count does not necessarily reflect the activity of the pulmonary infection. Except during acute episodes this measurement is not very

useful. In some cases the elevated count returned to normal levels after aureomycin therapy, but this was not a constant observation.

Roentgenograms

In most cases roentgenograms were taken previous to aureomycin therapy and at frequent intervals.

FIGURE 2 Roentgenograms of the Chest in Case 28 Taken before Aureomycin Was Started (Upper Film) and Three Months Later (Lower Film) Showing Improvement in the Extent of the Pulmonary Involvement

thereafter. Some improvement was seen, but this was not comparable to the excellent clinical response (Fig 2).

The Problem of Relapse

Aureomycin was discontinued in several patients after varying periods. Within three to seven days a relapse occurred, particularly in those with ex-

tensive pulmonary involvement. Readministration of the drug resulted in improvement. No refractoriness to the drug developed in this short period of observation.

Data from 2 patients are presented in Figures 2 and 3 to illustrate the nature of the response to aureomycin and to emphasize many of the statements made above. These figures are self-explanatory. In addition a summary of the treated cases arranged according to age of patient is presented in Table 3.

Figure 4 demonstrates the appearance of a patient (Case 19) taken before and after four weeks of aureomycin therapy with a dose of 125 mg twice

tration of aureomycin to small infants with pancreatic fibrosis to delay or prevent the appearance of pulmonary infection appears to be rational. It may likewise prove worth while to follow carefully the siblings of patients with known pancreatic fibrosis and babies with meconium ileus so that prophylactic aureomycin therapy can be instituted when indicated. That the drug can be given continuously over a long period without untoward effect has been demonstrated.

Although aureomycin is presumably effective because of its antibacterial properties, the persistence of the same bacterial flora in the nasopharynx despite the marked clinical improvement observed

FIGURE 3 Summary of the Course in Case 22 during the Period of This Study. Note that although penicillin aerosol and sulfadiazine did not control the respiratory symptoms, aureomycin repeatedly resulted in improvement in cough. It should also be noted that cessation of the drug or inadequate dosage caused a recurrence of symptoms.

a day. As in the remaining cases no other antibiotic was used concomitantly.

DISCUSSION

The introduction of a new, effective antibiotic in the management of patients with the pulmonary complications of pancreatic fibrosis simplifies the present mode of therapy. Inasmuch as the drug is effective in small oral doses and possesses few undesirable properties, it may become a most useful adjunct to the other therapeutic agents used in the treatment of this condition. The prompt return of symptoms when the drug is discontinued should be emphasized. That such an agent will be most effective when administered early in the course of the pulmonary disease is obvious. It is equally clear that the drug will be of little ultimate value in advanced bronchiectasis. Prophylactic adminis-

tration of aureomycin to small infants with pancreatic fibrosis to delay or prevent the appearance of pulmonary infection appears to be rational. It may likewise prove worth while to follow carefully the siblings of patients with known pancreatic fibrosis and babies with meconium ileus so that prophylactic aureomycin therapy can be instituted when indicated. That the drug can be given continuously over a long period without untoward effect has been demonstrated.

Although aureomycin is presumably effective because of its antibacterial properties, the persistence of the same bacterial flora in the nasopharynx despite the marked clinical improvement observed

in vivo exposure. However, these patients continued to show clinical improvement on the same dosage schedule despite increasing in vitro resistance.

The appearance of *Pr vulgaris*, *Ps aeruginosa* and fungi in the nasopharynx of patients treated with aureomycin, overgrowing or replacing the initial bacterial flora, is reminiscent of similar

of cough, improved general well-being, increased appetite and weight gain. An increase in the number and looseness of stools was noted in most patients. The drug had to be discontinued in 1 patient because of severe diarrhea. No other untoward effects were encountered. The discontinuance of the drug resulted in the prompt reappearance of symptoms

Note the improvement in nutrition and general appearance. The patient gained 4 pounds in four weeks.

phenomena that have been observed repeatedly during prolonged penicillin or streptomycin therapy.

SUMMARY

Aureomycin is effective in the management of the pulmonary involvement in pancreatic fibrosis.

Thirty-five patients treated with different oral doses were followed for periods varying up to four and a half months. The minimal effective dose ranged from 20 to 30 mg per kilogram of body weight given in one or two divided doses a day.

The response was good to excellent in 31 of the 35 cases. This was characterized by disappearance

Staphylococcus aureus was isolated from the nasopharynx of all patients included in this series. The clinical improvement was independent of the bacteriologic findings as determined by study of the nasopharyngeal flora. The in vitro sensitivity of the *Staph aureus* isolated from these patients was determined for penicillin, streptomycin and aureomycin. The majority of strains were relatively more sensitive to aureomycin than to either of the other two antibiotics. The *Staph aureus* isolated from 7 patients during aureomycin therapy showed an apparent increase in resistance ranging from fourfold to thirty-two-fold.

300 Longwood Avenue

tensive pulmonary involvement. Readministration of the drug resulted in improvement. No refractoriness to the drug developed in this short period of observation.

Data from 2 patients are presented in Figures 2 and 3 to illustrate the nature of the response to aureomycin and to emphasize many of the statements made above. These figures are self-explanatory. In addition a summary of the treated cases arranged according to age of patient is presented in Table 3.

Figure 4 demonstrates the appearance of a patient (Case 19) taken before and after four weeks of aureomycin therapy with a dose of 125 mg twice

tration of aureomycin to small infants with pancreatic fibrosis to delay or prevent the appearance of pulmonary infection appears to be rational. It may likewise prove worth while to follow carefully the siblings of patients with known pancreatic fibrosis and babies with meconium ileus so that prophylactic aureomycin therapy can be instituted when indicated. That the drug can be given continuously over a long period without untoward effect has been demonstrated.

Although aureomycin is presumably effective because of its antibacterial properties, the persistence of the same bacterial flora in the nasopharynx despite the marked clinical improvement observed

FIGURE 3 Summary of the Course in Case 22 during the Period of This Study. Note that although penicillin aerosol and sulfadiazine did not control the respiratory symptoms, aureomycin repeatedly resulted in improvement in cough. It should also be noted that cessation of the drug or inadequate dosage caused a recurrence of symptoms.

a day. As in the remaining cases no other antibiotic was used concomitantly.

DISCUSSION

The introduction of a new, effective antibiotic in the management of patients with the pulmonary complications of pancreatic fibrosis simplifies the present mode of therapy. Inasmuch as the drug is effective in small oral doses and possesses few undesirable properties, it may become a most useful adjunct to the other therapeutic agents used in the treatment of this condition. The prompt return of symptoms when the drug is discontinued should be emphasized. That such an agent will be most effective when administered early in the course of the pulmonary disease is obvious. It is equally clear that the drug will be of little ultimate value in advanced bronchiectasis. Prophylactic adminis-

tration of aureomycin to small infants with pancreatic fibrosis to delay or prevent the appearance of pulmonary infection appears to be rational. It may likewise prove worth while to follow carefully the siblings of patients with known pancreatic fibrosis and babies with meconium ileus so that prophylactic aureomycin therapy can be instituted when indicated. That the drug can be given continuously over a long period without untoward effect has been demonstrated.

Although aureomycin is presumably effective because of its antibacterial properties, the persistence of the same bacterial flora in the nasopharynx despite the marked clinical improvement observed

The development of bacterial resistance to aureomycin has not yet been definitely established, although observations on 7 of the patients in this series suggest that resistance can be acquired after

POSTERIOR TUBERCULOUS SINUSES OF VERTEBRAL ORIGIN*

Wound Revision and Closure with Streptomycin Permitting Early Spinal Fusion

JOHN J CINCOTTI, M D,[†] ARNOLD M SALZBERG M D,[‡] EDWARD W BOONE, M D,[§] AND JOHN B KELLEY, M D[¶]

RUTLAND HEIGHTS, MASSACHUSETTS

BEFORE the advent of streptomycin, half the patients having sinuses associated with Pott's disease died. Many procedures were devised and advocated for the control of tuberculous abscesses and sinuses but were uniformly characterized by poor therapeutic response. Aspiration of abscesses and excision of sinuses were followed by recurrence in about 60 per cent of the cases.¹⁻⁹ When such foci of soft-tissue infection presented near the site of tuberculous spondylitis, it was rarely possible to perform spinal fusion without considerable risk to the patient. Usually, in the face of this common complication, all thought of spinal fusion was abandoned. The only alternative was a prolonged and uncertain program of rigid immobilization, the patient being subjected to a variety of physical and chemical agents in an effort to control the tuberculous sinus.

Developments of recent years have greatly improved the outlook of the patient with tuberculous spondylitis. Spinal fusion continues to be the most effective method for control of the vertebral infection, but streptomycin therapy has proved extremely important in the control of the frequently associated infection of soft tissues.¹⁰⁻¹⁴ We are concerned in this study with the posterior tuberculous abscess or sinus complicating Pott's disease, which interferes, by threat of contamination, with the early, definitive care of the underlying vertebral disease. Prompt and effective relief of such posterior foci permits fusion of the spine and rehabilitation of the patient in a period often measured in terms of months rather than years.

Streptomycin will heal most tuberculous sinuses without adjunctive surgical measures, unless drug fastness has developed. However, such treatment is usually prolonged. Twelve of 15 sinuses in Hinchshaw's¹⁰ series closed without recurrence but the duration of treatment recommended was three to four months.

When Brock¹¹ used streptomycin and adequate drainage, 59 of 60 sinuses closed. Seventy per cent of these sinuses required ten to twenty weeks of drug administration to heal. In our clinic this regime

was followed with similar results, but we have found that the period required for healing by second intention with streptomycin may be reduced by surgical closure after adequate wound revision. Our results on secondary and primary closure of the excised tuberculous abscess or sinus with streptomycin therapy have been reported elsewhere.¹⁴

Since our previous report we have confirmed the value of this mode of management, and a much larger series of cases is available for clinical evaluation. In 2 out of 7 cases in which wound revision and primary closure was undertaken, reformation of an abscess under the firmly healed wound occurred. When a period of continuous decompression following débridement was allowed (from two to six weeks) before wound closure was undertaken, only 2 out of 26 cases presented recurrence of a sinus in the healed revision wound. One of these closed before completion of the first course of streptomycin, whereas the other, which was more profusely draining, closed during a second course of streptomycin given for another indication. Both have remained firmly healed. Thus, delayed closure is found, in general, to be the more effective procedure. The chronic, meagerly draining sinus, small in total extent, may be closed by excision and primary suture. When rapid reaccumulation of pus or excessive drainage presents clinically, adequate débridement and a period of continuous decompression are necessary before revision and secondary closure of the wound.

The effectiveness of streptomycin in the treatment of tuberculous sinuses has been improved by the observation of certain surgical principles. These principles are as follows: *superficial encapsulated tuberculous pus must be adequately drained; the tuberculous sinus must be widely deroofed; tuberculous granulation and fibrous tissue must be removed; and extravertebral necrotic bone and cartilage must be removed.*

GENERAL INDICATIONS FOR STREPTOMYCIN THERAPY

Management of the posterior tuberculous abscess or sinus by surgical measures and adjunctive streptomycin therapy varies according to the nature and location of the process. Several categories are met with, two or more of which frequently coexist in the same patient. Some of these abscesses and sinuses should be disregarded when spinal fusion is undertaken. Others require a staged surgical

On June 13 a 10-day course of penicillin was started consisting of 300,000 units a day. Six days later wound revision and secondary closure was performed. The sinus tract was removed surgically as far as the transverse process of the fourth lumbar vertebra. The fascial layers were developed and sutured without drainage. The wound healed firmly. On July 12 streptomycin was discontinued. A two-stage Hibbs spinal fusion was performed on August 27 and October 8. Convalescence was uneventful. The patient was discharged on March 25, 1948, and has remained well during the 17 months since the final operation.

CASE 3 H W K (R.H.V.A.H 19,758), a 32-year-old man, was admitted to the hospital on December 23, 1946, with a tuberculous sinus in the left posterior lumbar region. The eleventh and twelfth dorsal vertebrae showed osteo-mineralization, but the intervening disk was not thin. In addition there was a left tuberculous pleural effusion, and an apparently arrested, minimal lesion in the upper lobe of the right lung. On October 21, 1945, a left lumbar abscess had been drained. Smear, culture and guinea-pig inoculation were all positive for tubercle bacilli. The vertebral lesion had been diagnosed as tuberculous spondylitis, and a Bradford frame had been employed since December 13, 1945.

Lipiodol studies demonstrated that the sinus extended to the level of the disk between the eleventh and twelfth vertebrae, where it angulated forward to end in a small pocket. On March 14, 1947, chest x-ray study disclosed a diffuse haze through all lobes of the lungs, highly suggestive of miliary tuberculosis. By March 28, these granular markings had increased considerably and streptomycin, 20 gm a day, was begun. The clinical response was excellent, and radiologic clearing was demonstrated by serial chest films. Spinal fusion was then considered in an effort to utilize the favorable streptomycin response.

On July 15 the sinus tract was thoroughly debrided, revised and closed primarily without drainage. There had been no decrease in size of the sinus under streptomycin, but the amount of drainage had diminished considerably in recent weeks. Firm wound healing occurred by first intention. The course of streptomycin ended on July 27. The vertebral bodies of the eleventh and twelfth dorsal vertebrae had become more calcified, with considerable restoration of normal trabecular markings. Some anterior bone bridging was noted, and the paravertebral mass had decreased in size.

On August 15, the patient complained of malaise, nausea and headache. Lumbar puncture revealed an elevated spinal-fluid pressure, with 80 cells, predominantly lymphocytes, per cubic millimeter, a protein of 100 mg per 100 cc. and low sugar and chloride values. The fluid was positive for tubercle bacilli on smear of the pellicle and by culture and guinea-pig inoculation. The patient was transferred to the medical service, where a second course of streptomycin, intramuscularly and intrathecally, was begun. He responded well for 3 weeks but then began to fail. Spinal-fluid streptomycin levels ranged from 15 to 194 microgm per cubic centimeter. He died on November 23, 1947. The spinal-fluid organisms had become resistant to over 1000 microgm. of streptomycin per cubic centimeter.

At autopsy, the entire healed tract was carefully excised and studied. It included skin and the portion of the anterior vertebral ligament at the bone bridge. Many sections were studied by our consultant pathologist, Dr Raymond Goodale, and sections were sent to the Army Institute for special investigation. Both reports stated that there was no evidence of tuberculosis.

CASE 4 H G S (R.H.V.A.H 19,735), a 30-year-old man, was admitted to the hospital on April 3, 1947, for streptomycin therapy. He had had pulmonary tuberculosis since June, 1945, and a left artificial pneumothorax had been maintained since October, 1945. Tuberculosis of the left ninth rib had been diagnosed in July, 1946. Tuberculosis of the tenth and eleventh thoracic vertebrae, with a right lumbar abscess, was discovered in September, 1946. In February, 1947, a spinal fusion was performed, tibial grafts with nut-and-bolt fixation being used. Several weeks after operation the wound broke down and a soft mass appeared over the left iliac region. On admission the upper half of the dorsal spinal-fusion wound was separated and under-

mined, draining a moderate amount of tuberculous pus. There were rapidly reaccumulating, bilateral lumbar abscesses, which undermined the full thickness of the skin across the back.

X-ray study of the chest on admission showed a left pneumothorax and a pleural haze over the apex of the upper lobe of the right lung. Spinal films disclosed narrowing and irregularity of the disk between the tenth and eleventh dorsal vertebrae, the body of the former was irregularly mottled. There was a 12.5-cm., dense, intact bone graft to the left of the spinous processes of the eighth to twelfth dorsal vertebrae, and to the right there were two graft fragments secured by nut-and-bolt fixation. The right psoas shadow was not seen. There was an area of cyst-like rarefaction lateral to the upper angle of the left sacroiliac joint.

Drainage of the wound became slight, but smears and cultures of the wound and the lumbar abscesses were positive for acid-fast bacilli. No connection could be demonstrated between the wound and the lower lumbar abscesses. A 60-day course of streptomycin, 10 gm. a day, was begun on May 14. Two days later the wound was explored, excised and extended. The nut and bolt were easily movable and the right-caudal-graft fragment was loose and roughened. These were removed. The wound was closed without drainage and healed by first intention. On May 26 the right psoas abscess was widely drained, and the undermining symmetric lumbar collections of pus were counterdrained dependently. In all, over 1500 cc. of pus was removed. Revision and secondary closure was performed on June 18. All wounds remained firmly healed.

On August 12 films of the spine showed less mottling and some recalcification of the tenth dorsal vertebra. The paravertebral bulge was considerably less marked. The bone cyst in the left ilium was unchanged. The patient became ambulatory in a Taylor back brace.

On October 25, splenectomy was performed for acute, severe, idiopathic thrombocytopenic purpura. The patient died thirty-six hours postoperatively with a platelet-count rise to only 28,000. No accessory spleen was noted at operation. Permission for autopsy was not granted.

CASE 5 A. R. (R.H.V.A.H 20,155), a 50-year-old man with tuberculous spondylitis of the seventh, eighth and ninth thoracic vertebrae had had a spinal fusion of the sixth to tenth dorsal vertebrae performed in another hospital in June, 1944. He was discharged in January, 1945. He was next hospitalized in October, 1947, for a large fluctuant mass in the right costovertebral region. This mass was drained, and 800 cc. of tuberculous pus was recovered.

In November the patient was transferred to this hospital. He was seriously ill and had suffered a recent 15-lb weight loss. Spinal roentgenograms showed extension of the disease above and below the fusion area and a large paravertebral mass in the posterior mediastinal compartment. Exploration of the fused area and extension of the spinal fusion were contraindicated by the presence of the nearby draining sinus.

Streptomycin, 10 gm a day, was started on December 15, and the sinus was debrided and the abscess deroofed. Three weeks later the wound was revised and secondarily closed. On February 11, 1948 the fusion wound was explored, and a caudal extension of fusion from the eleventh dorsal to the twelfth lumbar vertebra was performed. There was no pseudarthrosis. Immediately after operation the patient became markedly depressed and unco-operative, vehemently resisting food and attempts at intravenous and gavage therapy. The fusion wound dehisced on the 14th postoperative day, and the sinus wound opened and began to drain 5 days later. Cultures were negative for pyogens and tubercle bacilli. With recovery of his mental status and under vigorous nutritional replacement therapy, the wounds healed rapidly. Pressure symptoms from his large paravertebral mediastinal mass became severe, requiring frequent aspirations. Streptomycin was discontinued on April 3.

On June 29, both twelfth ribs were removed because of tuberculous involvement. On September 15 the fusion was extended upward from the sixth to the fourth dorsal vertebra and a second course of streptomycin, 10 gm a day, for 42 days was initiated. With the fusion completed and because of an increase in the width of the paravertebral,

program geared to the effective zone of streptomycin therapy. It should be emphasized that the goal is the early fusion of a tuberculous spine.

The *paravertebral tuberculous abscess* under the anterior longitudinal ligament offers no contraindication to spinal fusion, nor does it of itself constitute an indication for streptomycin therapy except when spinal-cord compression complicates the problem. The tuberculous paravertebral mass frequently decreased in size under streptomycin therapy (Cases 3 and 4), so that streptomycin is indicated when signs of spinal-cord compression exist. Conversely, absence of clinical response to an initial course of streptomycin in the presence of a highly suspicious vertebral lesion and paravertebral mass, with signs of spinal-cord compression, suggests a nontuberculous etiology.* Less serious pressure manifestations of the space-occupying mass are easily relieved by repeated aspirations, without the use of streptomycin, until fusion is completed. Because of the prolonged drainage that follows costotransversectomy, even under months of streptomycin therapy in 2-gm daily doses,¹⁵ this procedure should be delayed, if possible, until the spinal fusion is completed (as in Case 5).

The *deep, burrowing extension abscess* (psoas and so forth) and its more superficial sequelae, which do not point or drain posteriorly, offer no contraindication to spinal fusion. This applies only so far as these infected zones do not present in the projected area of spinal fusion and are, therefore, no hazard from the standpoint of wound contamination.

The *posterior tuberculous sinus and the subcutaneous abscess with marked thinning of the skin, close to the proposed operative area*, have been established as contraindications to spinal fusion. When the tuberculous sinus is the entire and major problem, its management by secondary healing or surgical closure under streptomycin is elective. However, when the sinus is associated with Pott's disease and its proximity contraindicates required spinal fusion, indefinite delay of fusion is avoided by surgical closure of the sinus under streptomycin therapy. The major surgical procedure can then be performed in the safest zone of streptomycin therapy.

CASE REPORTS

This study includes 6 cases of tuberculous spondylitis in which spinal fusion was desirable. In each of these patients fusion was contraindicated by posterior, superficial tuberculous abscesses or sinuses immediately adjacent to the operative field. Two of the foci treated were situated in the posterior midline and the remaining sites ranged from 3 to

12 cm from the midline, with an average distance of 4 cm.

CASE 1 J W M (R H V A H 19,208), a 28-year-old man, was admitted to the hospital on June 20, 1946, with a diagnosis of bilateral pulmonary tuberculosis, moderately advanced.

A roentgenogram of the chest revealed bilateral apical infiltrations. The sputum was normal. Serial films showed progressive clearing and contraction of the apical disease during the next 3 months. In September the patient complained of pain in the right hip. Roentgenograms of the right hip were normal but the lumbar spine showed decalcification and erosion of the anterior surface of the body of the first and the upper border of the second lumbar vertebra, with irregularity and thinning of the intervertebral disk. A presumptive diagnosis of tuberculous spondylitis was made, and the patient was treated by bed rest and Taylor back brace.

In January, 1947, roentgenograms of the spine showed increased destruction of the first and second lumbar vertebrae and beginning involvement of the twelfth thoracic vertebra. The right psoas shadow was obliterated by a mass, presumably a psoas abscess. A 4-cm mass could be palpated in the right lumbar region. The mass rapidly increased to about 15 cm in diameter, undermined across the midline, and pointed above the right iliac crest. It was acutely tender. Frequent aspirations yielded tuberculous pus, and two draining sinuses developed.

On March 4 intramuscular injection of streptomycin was begun, the dosage being 20 gm a day. On the following day the right-psoas-muscle abscess was drained, and 1200 cc of green, creamy pus was recovered. The abscess occupied a space between the peritoneum and the lumbodorsal fascia, extending from the right tenth rib into the true pelvis. It had dissected to the left paravertebral region, superficially through Petit's triangle, and had undermined to the right anterior superior iliac spine. The right quadratus lumborum and psoas muscles were almost totally destroyed. A counter incision was used to drain a daughter abscess over the right posterior superior iliac spine.

During the next 2 months the small daughter abscess and its sinus tract closed, and the superficial undermining area across the midline healed solidly. On May 10, a 12-day course of penicillin was started, consisting of 300,000 units a day. Six days later the wound was revised, the sinus tract and abscess being partially excised, and was closed without drainage. Five weeks later a Hibbs spinal fusion was done from the tenth thoracic to the fourth lumbar vertebra. The fusion mass was supplemented by bone chips taken from the left ilium. Streptomycin was discontinued on July 22, after 140 days of administration. The secondarily closed sinus and the spinal fusion incision have remained solidly healed. The patient was discharged in December and has remained well during the 20 months since his last operation.

CASE 2 W J M (R H V A H 19,385), a 22-year-old man, was admitted to the hospital on September 11, 1946, with a diagnosis of Pott's disease of the fourth and fifth lumbar vertebrae, and left psoas abscess.

A roentgenogram of the chest revealed bilateral apical infiltration. The sputum was normal. Roentgenograms of the spine showed degenerative changes of the fourth and fifth lumbar vertebrae and a left paravertebral mass. A fluctuant, nontender, slightly warm mass, measuring 15 by 5 cm, was felt in the left lumbar region. This mass was centered over the left iliac crest and extended medially across the lumbar spine. The skin overlying the paraspinal region of the mass was thin.

On October 9 a diagnostic aspiration of the left psoas abscess was performed, after which the abscess ruptured spontaneously and began to drain thick, caseous tuberculous pus. Iodized oil injected into the sinus revealed a tract directed anteromedially, not quite reaching the fourth lumbar interspace.

On March 4, 1947, intramuscular injection of streptomycin, 20 gm daily, was begun. On the following day, debridement of the sinus was performed, and considerable diseased tissue was removed. The wound was packed loosely with iodoform gauze.

*G E W Jr (R H V A H 20,430) a 25-year-old man with progressing paraplegia associated with collapse of the tenth dorsal vertebra and a small paravertebral mass was transferred to this hospital with a diagnosis of tuberculous spondylitis after having been in two teaching hospitals. Two diagnostic aspirations of the mass yielded only blood. There was no clinical response to a 3-gm. course of streptomycin. Laminectomy decompression was then performed and biopsy of the involved vertebra revealed a primary malignant capillary hemangioendothelioma.

may occur with astonishing suddenness and is probably irreversible. We do not yet have statistically significant figures on resistance studies in patients exhibiting active involvement of several bodily systems, such as pulmonary, skeletal and genitourinary, who have received streptomycin therapy. Until such data are available, the emergence of resistant organisms from any source in a given patient must be presumed to mean that similar resistance does, or will before long, exist in organisms in other foci within the same person.¹⁷ Tuberculosis is a notoriously recurring disease involving many systems of the body. In the majority of cases, a brief course of streptomycin (measured in total grams) leaves one with a still potent agent for the treatment of unlooked-for complications in the same system or subsequently arising in other systems.

In an attempt to overcome these problems we have added wound revision and primary or secondary closure of the sinus to obtain a clean operative field through which early spinal fusion can be performed. Internal immobilization of the tuberculous vertebrae is accomplished with minimal delay and early in the course of streptomycin therapy. This immobilization will also accelerate healing of the secondary soft-tissue tuberculosis and probably reduce the incidence of sinus recurrence. Furthermore, preliminary study of non-orthopedic tuberculous sinuses suggests that surgical closure reduces the amount of streptomycin required for healing. With primary and secondary surgical closure of tuberculous sinuses, as little as five weeks of streptomycin therapy has sufficed.¹⁴

Recurrence of the sinus in some cases is likely and is an indication of continued activity of the tuberculous infection. In such cases a more intensive course of streptomycin may be required, but clinical judgment should be exercised if the presence of tuberculosis in extraskeletal systems presents other potentially major surgical problems. Maintaining a streptomycin-sensitive organism would then outweigh in importance the recurrence of a tuberculous sinus, particularly if the orthopedic operative problem had been solved. A patient now under observation illustrates this problem. Spinal fusion was performed in 1946 without the use of streptomycin therapy. In mid-1948 a tuberculous lumbar abscess, which drained spontaneously, developed. Roentgenographic examination showed the vertebral lesion to be in a healing phase. There was no extension of disease, and the fusion appeared solid. Observation over a period of months should enable us to decide whether or not further fusion is indicated. Until such a decision is made streptomycin will be withheld, and no surgical treatment of the sinus will be undertaken. If the sinus proves to be the entire problem, it can be readily managed as outlined above.

The ideal management of the problems presented in this study is often not possible. Long courses

of streptomycin were given in the earlier cases because of inexperience, and in the later cases because we had extended our indications for spinal fusion. The experience gained has served to focus our attention more firmly on the conservation of streptomycin through judicious application of cardinal surgical principles initiated at the optimum time. In the favorable case, a short course of streptomycin may well result in a firmly healed posterior tuberculous sinus and fusion wound. In the unfavorable case the indications for spinal fusion may be extended.

SUMMARY

A plan of management for the posterior tuberculous sinus of vertebral origin is described. Streptomycin is employed in a minimal total dosage through the application of established surgical principles, permitting spinal fusion to be performed early, in the safest zone of streptomycin treatment.

In the good-risk patient with a meagerly draining posterior sinus, excision and immediate closure under streptomycin protection result in a firmly healed wound. Spinal fusion may then be carried out early without danger of wound contamination.

In the good-risk patient with a copiously draining posterior sinus, adequate debridement and continuous decompression over a period of days are necessary. Subsequent wound revision and secondary closure under streptomycin therapy result in a firmly healed wound. Spinal fusion is thus but slightly delayed.

In the poor-risk patient with a posterior tuberculous sinus of vertebral origin, the unrestricted use of streptomycin may be necessary, but the plan of management permits spinal fusion early in the course of streptomycin therapy.

mass, a right costotransversectomy through the ninth and tenth ribs was done on November 15, draining the mediastinal abscess, with marked symptomatic relief. The patient became ambulatory on November 23. Both fusion wounds have remained firmly healed, and the mediastinotomy drainage has gradually diminished.

CASE 6 J L D (RHVAH 18,749), a 23-year-old man, was first hospitalized in January, 1945. A right artificial pneumothorax was attempted for active pulmonary tuberculosis. It was abandoned in May because of adhesions, and in July of that year the right phrenic nerve was crushed and artificial pneumoperitoneum begun.

He was transferred to this hospital on November 25. X-ray films of the chest revealed fibrosis and mottled infiltrations throughout all lobes of both lungs, with honeycombing in the upper lobe of the right lung. Examination of the sputum was negative on admission but became positive in May, 1946. A left pneumothorax was induced on July 1, and was satisfactory.

The first major surgical procedure performed on this patient was a right extrapleural pneumothorax on July 29, 1947, under streptomycin protection, 1.0 gm a day for 42 days. Three months later a right lumbar abscess developed. Repeated aspirations were negative for pyogens, fungi and acid-fast bacilli. The vertebral origin of this abscess could not be ascertained. Because of sinus-tract formation, a wide operative drainage was done on November 13. The right transverse processes of the lower lumbar vertebrae were found to be bare and spongy. Biopsy of the abscess wall showed tuberculosis.

By April 8, 1948, serial x-ray films revealed that the disk between the sixth lumbar and the first sacral vertebra was thin and showed erosion of the anterior inferior border of the sixth lumbar vertebra. A left anterior suprainguinal abscess formed, draining spontaneously after repeated aspirations but yielding negative cultures.

On April 15 the second course of streptomycin, 1.0 gm daily for 42 days, was begun. On April 21, secondary closure of the right posterior sinus was performed. The wound healed firmly. The anterior sinus offered no hazard of wound contamination to spinal fusion and was therefore disregarded. It healed spontaneously 20 days after completion of the second course of streptomycin. A Hibbs fusion of the fourth, fifth and sixth lumbar to first sacral vertebra was performed on May 12. Convalescence was uneventful. The patient became ambulatory with a Taylor back brace on August 11. He is asymptomatic, with a stable fusion, firmly healed wounds, right extrapleural pneumothorax, left intrapleural pneumothorax and a normal sputum since February 10.

GENERAL PROCEDURE

Bacteriologic and anatomic studies must precede streptomycin therapy in the surgical treatment of tuberculous abscesses and sinuses. The tuberculous nature of an abscess or sinus is established by diagnostic smear and culture, guinea-pig inoculation or biopsy. It should be stressed that an adequate specimen must be sent to the bacteriologist. Streptomycin-sensitivity studies are carried out. Radiopaque oil is frequently helpful in outlining the extent of the pathologic process.

The optimal conditions for wound healing are obtained by adequate hydration, high-protein and high-caloric diet, supplementary vitamins and the correction of anemia.

Streptomycin, 0.5 gm twice a day, and penicillin, 300,000 units daily, are given intramuscularly. Within three to seven days, the initial operation is conducted under general anesthesia. If the process is an *abscess*, it is incised and drained dependently. If the process is a *sinus*, its ramifications are derooft. In either event, the tuberculous granulation and fibrous tissue is removed. Lo-

calized pockets of purulent material are counter-drained if necessary. The open wound is packed loosely with iodoform gauze. The pack is removed in forty-eight hours and replaced by saline dressings. These dressings are changed daily, and the wound is irrigated.

Seven days after the first operation, the wound is revised and secondarily closed. The basic surgical routine is as follows: under general anesthesia, the skin margins are cut a few millimeters from the edge of the wound. The sinus wall is excised. The wound is thoroughly lavaged with saline. After a change of instruments, drapes, gowns and gloves, the fascial planes and subcutaneous tissues are developed into layers and closed with interrupted sutures of fine chromic catgut. An attempt is made to obliterate dead space. The skin is closed with fine-silk sutures without drainage. A pressure dressing is applied. Streptomycin is given until healing of the sinus appears complete.

Inasmuch as organism resistance is in direct proportion to the amount of streptomycin used, every effort should be made to keep the total dosage at a minimum. In the special problem of posterior tuberculous sinuses the optimum dosage of 1.0 gm of streptomycin daily may be reserved for the immediate operative period when closure of the sinus is accomplished. To protect the healed, surgically closed sinus wound, streptomycin should be continued at a reduced dosage schedule, until spinal fusion is performed, usually an interval of two or three weeks. The minimal safe but effective dose of streptomycin in this interval has not been established and probably varies with the activity of the underlying osseous lesion. Our present trend is toward the use of 1.0 gm of streptomycin every second or third day.

DISCUSSION

Posterior tuberculous sinuses associated with tuberculosis of the spine may present a specific problem. Spinal fusion frequently is not performed because of the presence of these superficial abscesses and sinuses in the projected operative area. Even with streptomycin and adequate drainage, spinal fusion is delayed because of the time required for healing by secondary intention. In addition, prolonged administration of streptomycin may be accompanied by drug toxicity and bacillary resistance.

Streptomycin is effective in the treatment of the early acute exudative lesion of tuberculosis caused by a sensitive organism, and hence is of value in operative procedures in which tuberculous dissemination may occur.¹⁶ Streptomycin resistance of tubercle bacilli occurs initially in a few untreated cases, and as early as the fourth week in organisms initially sensitive to (inhibited by) 0.5 microgm of streptomycin per cubic centimeter. Resistance is proportional to the total accumulated dose. It

and spleen had developed, the patient died with minimal and terminal involvement of the lungs

CASE 1 A 51-year-old man noticed, over a period of 4 months, malaise, low-grade fever, anorexia, loss of weight and periodic chilly sensations without frank chills

Physical examination showed a slight, general enlargement of all peripheral lymph nodes, and the ankles were moderately swollen and definitely red. No abnormalities were detected in the examination of the heart and lungs, but the spleen was palpable. A roentgenogram of the chest showed the widening of the mediastinum and enlargement of the hilar lymph nodes, with some diffuse peribronchial thickening (Fig 1)

The temperature was 103°F, the pulse 104, and the respirations 22, the blood pressure was 126/70

The red-cell count was 3,260,000, with a hemoglobin of 9 gm (58 per cent), and the white-cell count 5640, with 60

FIGURE 2 Gross Specimen at Autopsy, Showing Caseous Lymph Nodes and Terminal Miliary Lesions in the Lungs (Case 1)

per cent neutrophils, 12 per cent large lymphocytes, 24 per cent small lymphocytes and 4 per cent monocytes. Studies of the bone marrow showed a depression of all hemopoietic elements but no abnormal cells

A tentative diagnosis of inoperable bronchiogenic carcinoma or lymphoma of the lymphosarcoma type was followed by a therapeutic trial of 1500 r

The hilar infiltration increased slowly over a 10-week period. The temperature remained between 103 and 104°F for 8 weeks and then became remittent for the last 2 weeks. A noma-like lesion appeared on the right cheek during the 5th week of hospitalization. Final examination of the blood on the day before death showed a red-cell count of 2,630,000, with a hemoglobin of 7 gm (49 per cent), and a white-cell count of 2240, with 21 per cent segmented neutrophils, 33 per cent stab forms, 27 per cent juvenile forms, 12 per cent large lymphocytes and 6 per cent small lymphocytes

Autopsy revealed a primary tuberculous pneumonia in the lower lobe of the right lung, caseation of the mediastinal lymph nodes (Fig 2), generalized tuberculosis of the lungs, liver and spleen (Fig 3), serofibrinous tuberculous pleurisy and secondary fusospirochetal gangrene of the right cheek

In the following case the onset of primary progressive tuberculosis was insidious, with gradual

involvement of the lymph nodes and spleen, suggesting the diagnosis of a lymphoma of the Hodgkin type

CASE 2 A 30-year-old man moved from a rural area into an industrial center. About 6 months later malaise, a low-grade fever and a slight generalized lymph-node enlargement developed. A roentgenogram of the chest showed a definite widening of the mediastinum, and a diagnosis of lymphoma of the Hodgkin type was made. A biopsy of a peripheral lymph node showed a granulomatous reaction and definite tubercle formation. The clinicians interpreted the finding of tubercles in the lymph node as incidental and reaffirmed the diagnosis of lymphoma

The course of the disease, which was insidious in its beginning, now became more fulminating. There was marked malaise, anorexia, a spiking temperature and loss of weight. The patient became comatose and died 1 week later. The duration of the acute phase of the disease was a little over 8 weeks

Autopsy showed the presence of large caseous hilar lymph nodes (Fig 4), an enlarged, infected spleen, tuberculous meningitis and terminal miliary tuberculosis

The following case, an example of a chronic, progressive, primary tuberculosis with destructive lesions of the vertebrae, was incorrectly diagnosed as lymphoma, metastatic neoplasms or mycotic infection

CASE 3 A 40-year-old woman suddenly became ill 6 weeks before her first admission with chills, malaise and a temperature of 103 to 104°F. After penicillin therapy for 2 weeks and streptomycin for 1 week, the fever was reduced but not eliminated

On admission in October, 1946 the patient apparently was chronically ill, with slight tenderness in the epigastrium

FIGURE 3 Photograph of the Spleen in Case 1
The large white areas are tuberculous abscesses containing numerous tubercle bacilli

and the right upper quadrant. A roentgenogram of the chest showed a mass in the superior portion of the right hilus and another, smaller mass in the left hilar region

Examination of the blood revealed a red-cell count of 3,650,000, with a hemoglobin of 10 gm (69 per cent), and a white-cell count of 8500, with 75 per cent segmented neutrophils, 2 per cent eosinophils, 3 per cent monocytes and 20 per cent small lymphocytes. Studies of the bone marrow showed no abnormalities

PROGRESSIVE PRIMARY TUBERCULOSIS IN THE ADULT AND ITS DIFFERENTIATION FROM LYMPHOMAS AND MYCOTIC INFECTIONS*

DAVID T. SMITH, M.D.†

DURHAM, NORTH CAROLINA

THE death rate from tuberculosis in the United States has decreased from 200 per 100,000 in 1900 to approximately 30 in 1948. The present population is intermittently rather than constantly exposed to tubercle bacilli, consequently, an ever-increasing number of adults are found to be tuberculin negative.

Although conclusive statistical data are lacking, apparently the primary infection in the adult is predominantly an asymptomatic process. When

Occasionally, in the adult there is a steady relentless progression of the disease until all the internal organs are infected and death ensues.

In 5000 consecutive autopsies at the Duke Hospital, Durham, North Carolina the diagnosis of disseminated tuberculosis was recorded 40 times in adult patients. A review of the protocols shows that a number were examples of chronic fibrocaseous tuberculosis with terminal dissemination. In other cases the initial infection may have been a primary one, but the course of the disease and even the autopsy findings were indistinguishable from those of the ordinary chronic "reinfection" type of tuberculosis. After these questionable cases had been discarded a residue of 20 remained in which the extent and character of the lymphatic involvement was characteristic of a primary infection. There were 11 males and 9 females in this group, varying in age from eighteen to sixty. Five patients were white, and 15 were Negroes.

The relative frequency of this type of tuberculosis is emphasized by the observations that in the same series of 5000 autopsies, there were only 20 lymphomas of the Hodgkin type, 4 cases of Addison's disease and 4 of hemochromatosis.

It must be confessed that the clinical diagnosis in these cases of progressive tuberculosis was usually incorrect. Except for the 5 that terminated with a tuberculous meningitis, only 1 case was correctly diagnosed ante mortem.

Perhaps the most important point to remember in making the diagnosis is that primary disseminated tuberculosis can occur in the adult as well as in the child. With the possibility of tuberculosis in mind, one then looks for local and general lymphatic involvement, including an enlargement of the spleen. Whereas the hilar lymph nodes are frequently enlarged, the lungs show little if any infection until the terminal stage, and the sputum, if present, is almost invariably negative for tubercle bacilli.

The tuberculin test is positive in the early weeks and months of the disease but may disappear as the patient becomes exhausted. The white-cell count may be either elevated or depressed, but there is almost always a specific decrease in the small lymphocytes.

Some of the variations in individual cases are illustrated in the following case reports.

CASE REPORTS

In the following case after a high, continuous fever with progressive enlargement of lymph nodes

FIGURE 1 Roentgenogram of the Chest, Showing Widened Mediastinum and Enlarged Hilar Lymph Nodes in Case 1

lesions do appear in the lungs a few months after the conversion of a negative to a positive tuberculin test, they usually have the roentgenographic appearance of an ordinary, chronic type of adult or reinfection tuberculosis and follow a similar clinical evolution.^{1-5†}

involvement of the lymph nodes and spleen, suggesting the diagnosis of a lymphoma of the Hodgkin type

CASE 2 A 30-year-old man moved from a rural area into an industrial center. About 6 months later malaise, a low-grade fever and a slight generalized lymph-node enlargement developed. A roentgenogram of the chest showed a definite widening of the mediastinum, and a diagnosis of lymphoma of the Hodgkin type was made. A biopsy of a peripheral lymph node showed a granulomatous reaction and definite tubercle formation. The clinicians interpreted the finding of tubercles in the lymph node as incidental and reaffirmed the diagnosis of lymphoma.

The course of the disease, which was insidious in its beginning, now became more fulminating. There was marked malaise, anorexia, a spiking temperature and loss of weight. The patient became comatose and died 1 week later. The duration of the acute phase of the disease was a little over 8 weeks.

Autopsy showed the presence of large caseous hilar lymph nodes (Fig 4), an enlarged, infected spleen, tuberculous meningitis and terminal miliary tuberculosis.

The following case, an example of a chronic, progressive, primary tuberculosis with destructive lesions of the vertebrae, was incorrectly diagnosed as lymphoma, metastatic neoplasms or mycotic infection.

CASE 3 A 40-year-old woman suddenly became ill 6 weeks before her first admission with chills, malaise and a temperature of 103 to 104°F. After penicillin therapy for 2 weeks and streptomycin for 1 week, the fever was reduced but not eliminated.

On admission in October 1946 the patient apparently was chronically ill with slight tenderness in the epigastrium.

FIGURE 2 Gross Specimen at Autopsy, Showing Caseous Lymph Nodes and Terminal Miliary Lesions in the Lungs (Case 1)

per cent neutrophils, 12 per cent large lymphocytes, 24 per cent small lymphocytes and 4 per cent monocytes. Studies of the bone marrow showed a depression of all hemopoietic elements but no abnormal cells.

A tentative diagnosis of inoperable bronchiogenic carcinoma or lymphoma of the lymphosarcoma type was followed by a therapeutic trial of 1500 r.

The hilar infiltration increased slowly over a 10-week period. The temperature remained between 103 and 104°F for 8 weeks and then became remittent for the last 2 weeks. A noma-like lesion appeared on the right cheek during the 5th week of hospitalization. Final examination of the blood on the day before death showed a red-cell count of 2,630,000, with a hemoglobin of 7 gm (49 per cent), and a white-cell count of 2240, with 21 per cent segmented neutrophils, 33 per cent stab forms, 27 per cent juvenile forms, 12 per cent large lymphocytes and 6 per cent small lymphocytes.

Autopsy revealed a primary tuberculous pneumonia in the lower lobe of the right lung, caseation of the mediastinal lymph nodes (Fig 2), generalized tuberculosis of the lungs, liver and spleen (Fig 3), serofibrinous tuberculous pleurisy and secondary fusospirochetal gangrene of the right cheek.

In the following case the onset of primary progressive tuberculosis was insidious, with gradual

FIGURE 3 Photograph of the Spleen in Case 1. The large white areas are tuberculous abscesses containing numerous tubercle bacilli.

and the right upper quadrant. A roentgenogram of the chest showed a mass in the superior portion of the right hilus and another, smaller mass in the left hilar region.

Examination of the blood revealed a red-cell count of 3,650,000, with a hemoglobin of 10 gm (69 per cent), and a white-cell count of 8500, with 75 per cent segmented neutrophils, 2 per cent eosinophils, 3 per cent monocytes and 20 per cent small lymphocytes. Studies of the bone marrow showed no abnormalities.

Small doses of x-ray, followed by large doses, were applied over the hilar masses. The masses slowly disappeared, and 3 months after admission she was discharged afebrile and apparently improved.

During the next 3 months at home some lymph nodes appeared in the neck but disappeared spontaneously. The discomfort in the right upper quadrant continued, and a

FIGURE 4 Gross Specimen at Autopsy in Case 2, Showing Large Caseous Hilar and Peritracheal Lymph Nodes

new area of pain appeared beneath the lower third of the sternum.

Barium studies during the second admission in March, 1947, showed indentations in the esophagus suggestive of pressure by lymph nodes. She received 1250 r over this area and was discharged.

A low-grade fever persisted from March to July, and then a slight nonproductive cough, hoarseness and some difficulty in swallowing developed.

During the third admission in July, 1947, an x-ray film of the spine showed slight narrowing between the fifth and sixth cervical vertebrae. An examination of the larynx revealed a paralysis of the right vocal cord. A tuberculin test was performed, for the first time, and found to be positive in a 1:1,000,000 dilution of old tuberculin. Desensitization to tuberculin beginning with a 1:100,000,000 dilution and progressing to 1 cc of 1:1,000,000 was attempted.

The patient returned home, where she received 1 gm of streptomycin daily for 6 weeks. Striking improvement occurred while the streptomycin was being taken and for a few weeks after it was discontinued. She became afebrile, felt quite cheerful and returned to work on a part-time schedule. By November, however, severe pains appeared in the mediastinal region, which required Demerol as often as three times a day.

During the fourth admission, between January 6 and 12, 1948, she seemed quite well and was afebrile, but x-ray study showed a destructive lesion with partial collapse of the fourth thoracic vertebra.

The fifth admission, between January 28 and February 7, was characterized by low-grade fever and bilateral pleuritic pain.

The final admission was on July 15. The patient gave a history of being almost well in March and April followed by fever and vertebral pain in May. Streptomycin treatment for 3 weeks produced a remission, but a relapse soon occurred and streptomycin now was ineffective although continued for an additional 4 weeks.

Physical examination showed the patient to be quite ill, and the abdomen was distended and tympanic. The diaphragm was definitely elevated on the right, and films of the abdomen indicated that both liver and spleen were enlarged. She died on July 25, approximately 2 years after the beginning of her illness.

Autopsy revealed the residue of a primary tuberculous infection in the right upper lobe of the lung, scarred and fibrotic hilar lymph nodes and scarred and partially healed lymph nodes along the esophagus, and in the abdomen at the hilus of the liver. One of these lymph nodes was adherent to the stomach on one side and to the liver on the other. A rupture of this node into the stomach made a pathway for pyogenic organisms, which caused a large nontuberculous abscess in the liver. The destructive lesions in the bodies of the vertebrae were tuberculous and not neoplastic.

In the following case, the primary infection was in the cecum, and the presenting symptom was an appendiceal abscess followed by evidence of aplastic anemia and low-grade intermittent fever. Finally, the development of round lesions in the lungs suggested the diagnosis of neoplasia with pulmonary metastasis.

CASE 4 A 60-year-old man was admitted to the hospital in February, 1940, with a mass in the right lower quadrant. A diagnosis of appendiceal abscess was made and confirmed by operation 2 months later. The patient recovered from the operation but became progressively more anemic and did not respond to iron, liver extracts or multiple blood transfusions.

A filling defect found in the region of the ileocecal valve by barium studies persisted throughout his illness.

The lungs were normal for the first 2 years, but during the last 2 years small, round discrete areas appeared in the chest films. Some of these areas decreased in size, others seemed to change in shape and outline, and new ones appeared from time to time.

The patient had fifteen admissions for aplastic anemia over a 4-year period and finally died in circulatory collapse.

At autopsy tuberculous ulcers were found in the colon. The mesenteric, retroperitoneal and mediastinal lymph nodes

FIGURE 5 Gross Specimen at Autopsy in Case 4, Showing Round Areas of Tuberculous Infiltration Scattered through the Lungs

Apparently, the primary infection was present in the cecum and the hilar lymph nodes were not appreciably enlarged.

were caseous and contained tubercle bacilli. The spots in the lungs were tuberculous lesions (Fig 5). The spleen was enlarged and contained miliary tubercles. The bone marrow from the humerus was essentially normal.

DIFFERENTIAL DIAGNOSIS

The difficulty in differentiating primary progressive tuberculosis and some types of lymphoma is obvious. Moreover, in the past decade, it has been found that certain types of mycotic infections duplicate the clinical picture of progressive tuberculosis almost exactly. Histoplasmosis, coccidioidomycosis, sporotrichosis and South American blastomycosis all have a progressive fatal form characterized by enlargement of the lymph nodes and spleen. They also frequently show destructive lesions of the bones.

SKIN TESTS

Twenty-five years ago tuberculin skin tests were rarely employed in internal medicine because almost the entire adult population was tuberculinized. At the present time, however, there are many areas in this country where less than 50 per cent of the adults have a positive skin test. Except in obviously moribund patients, a negative test to 1 mg of old tuberculin or to the second strength dose of purified protein derivative practically eliminates the possibility of tuberculosis. One need not fear a false-negative test in the early stages of primary tuberculosis because the patient with primary tuberculosis does not develop symptoms until after the skin test becomes positive.

Skin tests with tuberculin-like antigens prepared from fungi are of definite but limited value in diagnosis. Positive skin tests develop quite regularly in persons who have had either a clinical or a subclinical infection with *Coccidioides immitis* or *Histoplasma capsulatum*, therefore, a negative skin test will eliminate the possibility of infection by these organisms unless the patient is in the terminal anergic phase of the disease. When concentrated antigens are injected into highly sensitized guinea pigs, cross reactions can be elicited with coccidioidin, histoplasmin and blastomycin.⁸ This suggests that there is a minimal amount of a common antigen in all three fungi. In the doses commonly used for skin tests, persons with positive skin tests to coccidioidin do not give cross reactions with histoplasmin and blastomycin. However, *Blastomyces dermatitidis* and *H. capsulatum* share a larger amount of a common antigen.⁹ Subjects who have had a subclinical infection with *H. capsulatum* usually react both to histoplasmin and to blastomycin, although in my experience the size of the reaction to blastomycin is always smaller and disappears completely if more dilute antigens are used for the test.

COMPLEMENT FIXATION

In contrast to the skin test, complement-fixing antibodies either do not appear or disappear shortly after a subclinical or mild primary clinical infection with *C. immitis*¹⁰ and *H. capsulatum*.¹¹ However,

in the progressive form of the disease the complement-fixing antibodies are regularly present, and the titer persists even when the anergic phase appears and the skin test becomes negative. Cross complement fixation is not observed between patients having coccidioidomycosis and histoplasmosis. Most patients, however, who fix complement to high titer with histoplasmin antigen also fix complement with the blastomycin antigen, but always at a lower titer.¹¹

The complement-fixation test for tuberculosis is not reliable, but the new agglutination test introduced by Middlebrook and Dubos¹² may prove to be extremely useful in early diagnosis.

BIOPSIES

If an enlarged lymph node is accessible a biopsy usually makes the differential diagnosis. The biopsy is particularly valuable in separating out the cases of sarcoidosis (Boeck's sarcoid) that may have been included with the lymphomas because the tuberculin test was negative.

The biopsy specimen should be cultured for tubercle bacilli and fungi. A culture is essential for the diagnosis of sporotrichosis, since the organisms are almost never seen in sections of human tissues.¹³

CULTURES

All the yeast-like and mold-like fungi will grow on both 1 per cent dextrose agar and on blood agar at either room or incubator temperatures. Since growth may be very slow, the culture should be inspected every few days up to a maximum of thirty days.

SUMMARY

With the rapidly increasing number of persons reaching maturity without becoming infected with tubercle bacilli, a larger number of adults will be found on the general medical wards with progressive primary tuberculosis. These cases resemble quite closely lymphoma of the Hodgkin type, progressive coccidioidomycosis and histoplasmosis, and, to a lesser extent, leukemia, aplastic anemia, metastatic neoplasm and sarcoidosis.

Before the discovery of promizole and streptomycin, the diagnosis of progressive primary tuberculosis was of academic interest only, but now, with a reasonably early diagnosis, some of these patients can be cured.

HOSPITAL ADMINISTRATION AS A MEDICAL SPECIALTY*

T STEWART HAMILTON, M D †

NEWTON LOWER FALLS, MASSACHUSETTS

HOSPITAL administration as a medical specialty seems to be disappearing. The change may be more relative than actual, as able lay administrators become increasingly interested in an expanding profession, but few physicians, it seems, even consider the possibility of hospital administration as a career. What does the specialty offer? Should it be abandoned to trained laymen? In the search for answers to these questions, a brief review of the past history and the present status of hospitals and hospital administration may be of value.

One of the first hospitals of which there is record was founded by Justinian in Rome in 369 A. D. The first known hospital on this continent was established in Mexico by Cortez in 1524. A hundred and twenty years later the Hôtel Dieu was opened in Montreal. The first general hospital in the colonies was the Pennsylvania General Hospital, founded at Philadelphia in 1756. In 1811 the first general hospital in Massachusetts and the third in the United States was founded; it was opened in 1821 and still stands as a tribute to the Reverend John Bartlett and the two physicians, Drs. Charles Jackson and John C. Warren, who were instrumental in its establishment, as well as to the many who since then have added to its fame.

Since its beginnings in this country, the voluntary hospital has been rather an anomaly. It is founded and operated (at a loss) as a charity, it is supported by the time, skill and funds of physicians, individuals, businesses and lately by Community Chests; it is governed by a board of trustees, usually laymen, it often functions not only as a hospital but also as a health center for the area it serves. The hospital has often been referred to as "the physician's workshop." Could one imagine a manufacturer inviting workers into his plant to work for themselves with his equipment and his personnel? In a modified way this is the relation between the physician and at least the smaller hospitals. Although physicians care for service and private patients, the trustees

have the final responsibility for everyone and everything in the hospital. They must hand down the policies by which the hospital operates and are, potentially at least, responsible for the adequate care of every patient, service and private. To execute the details of operation the trustees usually engage an administrator, who in turn supervises the operations of the hospital. He works with the staff to ensure adequate care of patients, to stimulate research and to co-ordinate the multiple aspects of the small city under his guidance. In addition, of course, he is concerned with purchasing and personnel, and may well have the added problems of an educational institution—at least a school of nursing, if not other more advanced medical-teaching programs.

How did this administrator come to be, and what is happening to him? In the early days, when hospitals were operated solely for the poor, a resident physician was usually engaged. His duties were to care for the patients and to administer the institution. It was preferable that he be married in order that his wife might serve as matron and housekeeper. As hospitals enlarged, both the operation of the institution and the care of the patient became much more complex. Gradually a division took place until the administrator was no longer directly responsible for the medical care of the patient. It is only in relatively recent times, however, that administrators have gathered together as a specialty group to establish uniform practices. The American Hospital Association held its fiftieth convention only last year. Thus, it is within the memory of many still living that hospital administration as a specialty and as a career has become known.

In 1933 a group of men meeting in Chicago formed the American College of Hospital Administrators, an organization to "establish high professional standards and to further the education of those in the hospital field." In the last sixteen years this organization has done much to advance the profession.

*Presented at the annual meeting of the Massachusetts Medical Society, Worcester, May 24, 1949.

†Director, Newton-Wellesley Hospital.

Several universities have recently offered courses in hospital administration. The first successful course was established by Dr A G Bachmeyer at the University of Chicago. At present courses are also offered at Yale, Columbia, Washington, Minnesota, Northwestern and other universities. They consist of one year of didactic teaching followed by a year of internship in an approved hospital. Although the instruction is open to physicians, enrollment consists almost exclusively of laymen. Upon successful completion of the course, the student receives a master's degree in hospital administration. In contrast to these formal courses several hospitals have for many years offered to physicians apprenticeships in hospital administration, among these are the Peter Bent Brigham Hospital and the Massachusetts General Hospital.

When a man has completed his schooling or his apprenticeship, or both, he may be chosen by a board of trustees as director of a hospital. He then stands, as the American College of Hospital Administrators has put it, at the helm of the hospital, as others have put it, he is ground between the upper millstone of the trustees and the nether millstone of the staff. Neither description is completely accurate. Given a good board of trustees (and it never ceases to be impressive how loyal and understanding such a group of civic-minded citizens can be), he may if he is a physician, "sit on the sidelines and watch the game," but he often has a better view than the man in the line. What are the disadvantages and the advantages of such a specialty for a physician? A few that come to mind are as follows:

Disadvantages

He is not in business for himself and is subject to dismissal. As in any appointive position, his success (or failure) proceeds more by steps than by the gradual change usual in active practice. Every physician, however, has the same opportunities to succeed or to fail. To be sure, the administrator is working for a small group who have the power to hire and to fire, but his chances of proving his worth to a small group may well be greater than those of a physician to the general population of the city or town where he practices. Given a good board, and most hospitals have them, the hospital administrator will have every chance to show his capabilities and to grow in his chosen specialty. Should his situation for any reason become intolerable, he can usually effect a change without the financial loss entailed in relocating a practice.

His income is limited compared to that of a physician in some other specialty. This is very true, but although the peak may not be so high, he will probably do at least as well in the early years. Taxes being what they are today, this is perhaps better. His income depends upon the

wishes of his trustees as well as his ability, this may be a disadvantage.

He must adjust himself to the personalities of trustees, staff personnel and patients. At times these adjustments may be very difficult, but do not physicians have all of them to some degree no matter what phase of medicine they choose?

He must operate a business. This is probably one of the greatest (if not the greatest) drawbacks for a physician. Most doctors go into medicine, in part at least, because they are idealists and rather shun the business side of life. The administrator must operate a big business — one of the largest in his community. He must operate it as economically as possible, and yet never with thought of profit. If he should operate in the black, he must give thought at once to a reduction in rates, for profit is not a purpose of a voluntary hospital. The multiple, complex problems of staff and personnel relations, wage schedules, purchasing, maintenance and all the others are with him constantly. To be happy in hospital administration a physician must enjoy business life to a certain extent.

He sits on the sidelines and watches the game being played. This, also, is one of the greatest disadvantages. The administrator must be willing to give up active, personal care of patients. He must, although using his knowledge as background, defer to his chiefs of services in matters of medical opinion. This disadvantage is balanced to some considerable extent by the first of the advantages noted below.

Advantages

He has an instrumental share in an enterprise greater than is possible (except for rare instances) in practice. Although he sits on the sidelines he has, throughout his career, a voice in calling the plays, in directing the progress of medicine in the hospital with which he is associated. From the professional side the course that is taken by his hospital during his tenure of office is in his hands to a greater degree than it is in the hands of any other staff member. What he may lose in the individual care of the patient, he gains in the setting of broad, over-all policy.

Community responsibilities. As director of a hospital today the physician, perhaps even as much as the public-health officer, represents to his community the general field of health. He serves on committees and organizations, he speaks to groups. Since he is not in practice he can take a much more active part in this phase of community life without fear of being unethical. As health has joined food, clothing and shelter to become the fourth necessity of life, so it is increasingly important that the story of health services be properly presented to an interested

MEDICAL PROGRESS

VIRAL INFECTIONS CONTRACTED IN THE LABORATORY*

S EDWARD SULKIN, PH.D.† AND ROBERT M. PIKE, PH.D.‡

DALLAS, TEXAS

THE increased interest in viral diseases in recent years, particularly in the field of laboratory diagnosis, has stimulated more and more laboratories to undertake work with these agents. Diagnostic procedures that formerly were to be found only in periodicals have now been collected in a single volume by Francis and others¹ who present them in a manner for ready reference for the average worker in the diagnostic laboratory. The availability of antigens² for use in the complement-fixation test makes it possible for any laboratory familiar with this technic to detect an increased antibody titer for a number of viral agents. Because work on viruses gives promise of continuing to expand rapidly, it seemed timely to call attention to the possibility of laboratory infection by reviewing cases that have occurred in various laboratories in the hope that such information would indicate where the greatest need for caution exists. Furthermore, recognition of the causes of such accidents, as far as they are known, may stimulate confidence on the part of those who would otherwise be discouraged from attempting such work.

A number of cases of laboratory infection have been reported in the literature. Early in our survey, however, it became apparent that numerous cases have been observed that have not been reported. Accordingly, an attempt was made to obtain information regarding such cases. The gratifying response to the inquiry on the part of various investigators in this field has added considerable information.†

No exhaustive attempt has been made to survey the situation regarding laboratory infection with organisms other than viruses although it is well known that many such infections have occurred, particularly with the brucella group³⁻⁵ with *Pasteurella tularensis* and *Past. pestis*^{4, 5} with *Bacillus anthracis*,⁶ with the typhoid bacillus⁷ with *Malloomyces mallei*⁸⁻¹⁰ with leptospira^{11, 12} with the borrelia,¹³ with *Treponema pallidum*,¹⁴ with *Coccidioides immitis*¹⁵ and doubtless with the tubercle bacillus and numerous other micro-organisms.¹⁷⁻¹⁸

The hazards involved in work with rickettsias have also been recognized. Virtually all laboratories working with typhus rickettsias have experienced infections among the personnel.^{19, 20} *Rickettsia prowazekii*²¹ and *R. nooseri*^{21, 22} have been responsible for such cases. Vaccination does not, apparently, entirely remove the risk of infection,^{23, 24} but the disease in vaccinated persons tends to be milder^{25, 26} and the incidence of infection is decreased.²¹ Laboratory infections with *R. tsutsugamushi* (*R. nipponica*)²² *R. rickettsi* (*Dermacentrophenus rickettsi*)²³ *R. conorii*²⁴ and *R. quintana*²⁵ have also been reported. The first known human infection with the agent of American Q fever occurred as a laboratory infection.²⁶ Other laboratory cases of Q fever have occurred in Australia²⁷ in the Mediterranean area²⁸ and in this country.²⁹⁻³¹ Even the most recent addition to the Rickettsia group *R. akari*, has been responsible for 2 cases of rickettsialpox in the laboratory.³²

Cases of viral infection that are believed to have been contracted in the laboratory are summarized in the accompanying Table 1 and 2. Those accidentally acquired outside the laboratory, such as the cases of encephalitis among veterinarians reported by Meyer¹³³ and Sulkin¹³⁵ and the case of equine infectious anemia in a person who had had contact with infected horses,¹³⁷ together with the numerous cases of psittacosis^{136, 138} among bird handlers, have not been included. In a few cases as indicated in the tables, there is some doubt that the infection was acquired in the laboratory, but the possibility seemed strong enough to warrant its inclusion. The etiology was proved in most of the cases by one or a combination of the following technics: isolation of the virus, demonstration of a significant rise in neutralizing or complement-fixing antibodies in blood samples obtained during convalescence as compared with those drawn during the early phase of the illness, or demonstration of a significant antibody titer in a single sample of serum in a person who presented a typical clinical course of the illness in question together with evidence of exposure to the viral agent. In cases in which this evidence was lacking, there was little doubt regarding the nature of the infection.

In all 222 cases with 21 deaths have come to our attention. Of the numerous viral agents involved, 5 have accounted for over two thirds of the infections — namely, yellow fever, Rift Valley

*From the Department of Bacteriology and Immunology and Virus Research Laboratory, Southwestern Medical College.

†Professor of bacteriology and chairman, Department of Bacteriology and Immunology and director, Virus Research Laboratory, Southwestern Medical College.

‡Associate professor of bacteriology and immunology, Southwestern Medical College.

§At the present time a number of viral antigens for use in the complement-fixation test are available commercially.

¶We are indebted to the many workers in the field who contributed the data that made this review possible.

public The hospital director is constantly called upon to perform this civic duty

His income is steady Although he will never amass a fortune—and few doctors do—he is assured of a regular income, regular vacations and often the benefits of sick leave and retirement His income is in many ways more secure than that of his fellow physicians

His contacts are pleasant In this aspect he differs little from the practicing physician

His hours of work are better than those of most physicians He is better able to schedule his time and can usually expect to work a more or less regular week Meetings, often in the evening, and on-call coverage may be somewhat confining, but these, too, can usually be scheduled By and large the physician administrator sees more of his family than the physician in practice does

He has counsel available should he need it The help that the administrator has available from his staff is obvious, in addition, if his board of trustees is a broad, representative body, he can, if he chooses, call upon any of several members for assistance in problems ranging from finance through personnel to workmen's compensation insurance He rarely needs to sail without guidance on uncharted seas The degree to which he may do so usually depends upon the man himself

Are physicians interested in the future of hospitals? They must be, for hospitals are so increasingly intimately connected with the practice of medicine that neither can stand alone If doctors are vitally interested in the future of hospitals, must they not be equally interested in their operation? The administration of the hospitals in this country is being taken over more and more by able lay administrators This is not because medical administrators are so poor, but because they are so few If those with no prior medical experience are recognizing the opportunities of this profession, are physicians not derelict in their duty if they do not bring its opportunities before medical students, interns and residents?

Given other qualities that are equal, it seems logical that since a hospital's prime reason for existence is care of the sick, a man with a medical background should make a better hospital administrator than one without In the interests of the future of hospitals, therefore, and in the interests of medicine as well, it behooves physicians to keep the opportunities of this too often forgotten specialty before themselves and before those who follow them While recognizing the importance of having able laymen in the field of hospital administration, they should reverse the trend of decline of hospital administration as a specialty chosen by physicians The first step in such a program is to present the specialty for consideration to medical students, interns and residents

fever, psittacosis, Venezuelan equine encephalomyelitis and lymphocytic choriomeningitis. The laboratory infections with yellow-fever virus have previously been reviewed by Berry and Kitchen.⁹² It is of interest to note that, to our knowledge, no cases of laboratory-acquired yellow fever have occurred since introduction of vaccination. Also, it has been suggested that the use of the lyophilic process for drying of infectious material may have contributed to the eradication of this danger.¹⁵⁹ This provides an excellent illustration of the possible elimination of a hazard by improved technique.

experimental use of the virus.¹⁶² The 3 cases of vaccinia observed by Beard⁸⁹ occurred in persons handling large amounts of highly concentrated rabbit-adapted virus.

In several cases a virus disease was first recognized among laboratory personnel.* The 6 cases of infection with louping-ill virus were the only known human cases until 2 naturally acquired cases were reported in 1948.¹⁶⁴ The first infections with the Newcastle disease virus among human beings observed were laboratory infections involving the eyes.† Until the recent report by Howitt and her

*Family name recommended by Breed et al.¹²³

†Numerous infections have occurred among dealers in birds.

‡The disease developed in 44 per cent of the personnel of a research laboratory in one building at the National Institute of Health.

§Rivers et al.¹⁵⁹ refer to infections that occurred in the laboratory of Dr. Krumwiede (New York City Department of Health) no details were given.

Recently, other workers¹⁶⁰⁻¹⁶¹ suggested improved procedures designed to remove the risk involved in the preparation of complement-fixing antigens.

The 24 cases of infection with Rift Valley fever virus point to the high infectivity of this virus, but none of the cases observed by Smithburn¹¹⁶ were severe. Death in the case reported by Schwentker and Rivers¹¹¹ occurred after recovery from the initial illness and was due to pulmonary embolism. Although many cases of ocular infection with vaccinia virus, usually associated with vaccination, have been reported, this infection rarely occurs as a laboratory accident in the course of preparation or

associates,⁹¹ the only naturally occurring human infections with this virus were also eye infections. The laboratory infections reported by these investigators were influenzal in nature, whereas the cases acquired outside the laboratory involved the central nervous system.

The original source of the "D" virus isolated by Durand⁸¹ in 1939 from his own blood during

*The first definite human infections with the virus of *Aujeszky's* disease (pseudorabies) were 2 cases of laboratory infection.¹⁶³ The virus was recovered from the blood in 1 case.

†Freymann and Bang¹⁶⁴ have reported 3 additional cases of conjunctivitis due to the virus of Newcastle disease in laboratory workers. The virus was isolated from 2 of these patients and antibodies were demonstrated in all 3.

a febrile illness is unknown. This agent, which was responsible for a single proved laboratory infection,⁵² has not been encountered in recent years.

The summary presented in the tables shows that the exact mode of infection in many cases is unknown, recognized accidents accounting for only 27 of the cases. The fatal case of encephalomyelitis reported by Helwig¹⁵ resulted when chick-embryo virus was thrown out of a centrifuge. The accidental splashing on the face of material from infected eggs was responsible for another case of encephalomyelitis¹⁶ and for 2 cases of infection with the virus of Newcastle disease.⁵⁷⁻⁵⁸ Three of the cases of lymphocytic choriomeningitis were associated with known accidents. In one,⁵⁷ a piece of glass flew into a worker's eye while infected guinea-pig organs were being ground in a mortar, in another⁵⁸ a celluloid tube containing the virus was flamed and in the third⁵⁹ the skin of the leg was accidentally punctured with a needle containing infectious material. The circumstances leading to a case of infection with psittacosis virus were carefully reconstructed by Rosebury and his associates¹³¹ to show how a leaking ampoule containing a suspension of volk-sac virus had contaminated the worker's hand and surrounding atmosphere. In the single case of B virus infection⁶¹ the worker was bitten on the finger by an apparently normal monkey. The bites of experimentally infected mosquitoes were thought to be responsible for 3 of the laboratory infections with yellow-fever virus.^{92, 100, 102} Contamination of the mouth by suction, a common laboratory accident, accounted for 1 case of influenza,¹⁰⁴ 1 case of mumps¹²¹ and 1 case of viral diarrhea.¹³² These instances illustrate the manner in which such accidents can occur, and suggest the nature of the precautions that should be taken by the laboratory worker handling infectious material.

The cases of infection among laboratory personnel apparently contracted during the handling of infected chick embryos attest to the potential infectiousness of such material. Chick-embryo virus was thought to be the source of infection in 2 cases of Western equine encephalomyelitis^{45, 46} in 4 cases of infection with Venezuelan equine encephalomyelitis virus⁵² and in the 1 case of Eastern equine encephalomyelitis.⁴⁹ Among the cases of psittacosis, of particular interest is a patient who had handled infected birds and mice for four years without infection but who became ill with proved psittacosis eight days after working with a suspension of virus from chick membranes.¹⁴⁰ The single case of meningopneumonitis-virus infection occurred in a person who had been using chick embryos for complement-fixation tests.¹³⁴ Seven cases of conjunctivitis due to Newcastle virus resulted from handling of infected chick-embryo fluids although Shumkin⁷⁰ referred to similar cases among kitchen workers handling food. Three cases of laboratory infection with the agent of lymphogranuloma venereum oc-

curred among persons working with infected chick embryos.¹⁴⁹ One factor that contributes to the danger in handling infected embryonated egg tissues may be the high concentration of virus in such material.¹⁶⁶

Several incidents show that a virus may retain its infectiousness for man even after many passages through animals. The strain of virus of Venezuelan equine encephalomyelitis responsible for the 8 infections reported by Lennette and Koprowski⁵¹ had been passed through mice about fifty times. The virus responsible for a case of Rift Valley fever had been through four hundred mouse passages¹¹² and another case at least three hundred mouse passages.¹¹⁵ The laboratory case of yellow fever reported by Theiler¹⁰³ was probably caused by mouse-adapted virus in the thirty-second passage. Influenza virus recovered from the person who contracted the disease from infected ferrets was pneumotropic when transferred back to the ferret.¹²² The alteration of the virus during animal passage, in this case, had not destroyed its infectiousness for man. Burnet and Bull¹⁴⁷ on the other hand found that passage of influenza virus through chick embryos rendered it noninfectious on intranasal instillation in man. Repeated passage of many viral agents in chick-embryo tissues may result in decreased virulence for the natural host.^{165, 169} In each of the 3 cases of poliomyelitis acquired in the laboratory the patient had been exposed to recently isolated strains.⁹⁻⁵⁵ During the two decades following the isolation of this virus the majority of work on experimental poliomyelitis was carried out with strains that were well established in the monkey in recent years, however, many investigators have attempted isolation of the virus from the patient. Coincidentally, the laboratory infection reported by Sabin and Ward³ in 1941 is the first recorded case of infection as a result of exposure to the virus in the laboratory. A second case of accidental infection with the virus was reported by Wenner and Paul⁵¹ in 1947, and more recently, we were advised of a third case by Gear.⁵⁵ In each case the patient had been exposed to strains of poliomyelitis virus recently isolated from human cases. For this reason workers in the field are cautioned to observe the greatest care in handling tissue or excreta of human subjects and in working with monkeys infected with this agent.

An analysis of the circumstances leading to certain of the laboratory infections has provided important information regarding the transmission of these diseases. Since contaminated dust from mouse cages was apparently responsible for the 8 infections with the virus of Venezuelan equine encephalomyelitis reported by Lennette and Koprowski,⁵¹ it seems likely that infection was by the respiratory route. Additional evidence for this possible route of infection is the fact that the virus was recovered from the nasopharyngeal washings

of 1 of the patients studied by Casals and his associates⁶⁰ and from 1 of the patients of Koprowski and Cox.⁶² The possibility of direct transmission of the equine-encephalomyelitis viruses suggested by these observations is of interest in connection with the evidence for insect and other ectoparasite vectors in these diseases.¹⁷⁰⁻¹⁷³

In addition to these cases of recognized illness, there have been an unknown number of inapparent infections as shown by the acquisition of antibodies by numerous laboratory workers. For example, Oltzky and Morgan⁴⁹ found protective antibodies for Eastern equine encephalomyelitis virus in the blood of 1 out of 6 laboratory workers who had handled the virus for several years. To account for this finding, they suggest the possibility of viremia without invasion of the central nervous system. Another case of antibodies for the same virus in a laboratory worker without recognized illness was recorded by Wright.⁴⁷ Beard⁸⁹ observed 2 inapparent infections with the virus of Eastern equine encephalomyelitis and 1 with the Western equine virus. Seven persons who had worked with the virus of Venezuelan equine encephalomyelitis, 1 who had bottled formalin-treated vaccine and 1 who had performed postmortem examinations on horses dying of encephalitis showed neutralizing antibodies for this virus. Only the last had an illness that was recognized as probable encephalitis. The serum from 6 persons residing in the same locality but who had no laboratory contact with the virus showed no mouse protection.¹⁷⁴ A number of subclinical infections with the Western equine encephalomyelitis virus evidenced by positive neutralization tests occurred among workers producing large amounts of vaccine of chick-embryo origin.¹⁷⁶ Neutralizing antibodies for the virus of St. Louis encephalitis have appeared in the blood of a person who worked with this virus intermittently for seven years.⁷⁰ In this laboratory the development of neutralizing antibodies for equine encephalomyelitis virus has been observed in a person who worked with the virus without clinical signs of infection.⁶⁶

A number of inapparent infections with the lymphocytic-choriomeningitis virus have been reported in animal caretakers.^{76 176 177} At a time when 2 fatal laboratory infections with the virus of lymphocytic choriomeningitis occurred, a number of inapparent infections were detected by serologic study among other members of the laboratory personnel.^{79 80} An inapparent infection with the virus of louping ill occurred at the same time as 3 apparent laboratory infections.^{84 85} One person working with the virus of Ilheus encephalitis developed a significantly high titer of neutralizing antibodies for this virus.^{118 178} An inapparent infection with mumps virus in a technician engaged in performing complement-fixation tests for mumps was reported by Enders and his associates,¹²¹ and another case was observed at the Pasteur Institute at the same

time that an overt infection occurred.⁸⁴ Two persons working with West Nile virus developed neutralizing antibodies without clinical symptoms.¹⁷⁹ A positive Frei test was recorded in a person a few months after he began working with the agent of lymphogranuloma venereum.¹⁸⁰ Four inapparent infections with the virus of Newcastle disease occurred at the time when 6 possible laboratory infections were observed.⁹¹ One investigator contracted an inapparent infection with the virus of Russian spring-summer encephalitis while working with the agent.¹⁸¹ In contrast to the above experiences, in some laboratories in which extensive virus work has been done no accidental viral infections have occurred, nor has there been evidence of inapparent infection.^{84 127 182-184} Although work with the rabies virus is done in many laboratories, to our knowledge there are no recorded cases of laboratory infections other than those acquired by persons carrying out post-mortem examinations on naturally infected animals.

SUMMARY

From published reports and from personal communications, 222 laboratory infections due to viruses are summarized. There were 21 deaths. The numerous viral agents involved include many that have been extensively studied, with the notable exception of rabies. Five viruses—namely those of psittacosis, yellow fever, Rift Valley fever, lymphocytic choriomeningitis and Venezuelan equine encephalomyelitis—accounted for over two thirds of the cases. An analysis of the probable source of these infections revealed that at least a third of the patients had become infected while handling infectious animals or tissues, 30 were presumed to have been exposed to a contaminated atmosphere, 13 had handled infectious material from patients, and 19 had worked with material from infected chick embryos. Known accidents were responsible for only 27 of the cases, these include a variety of situations, the most common involving the splashing of infectious material in the face or eyes. The first recognized cases of human infection with the viruses of louping ill and Newcastle disease were contracted in the laboratory. The data also reveal information regarding incubation periods and the route of infection in certain viral diseases.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35311

PRESENTATION OF CASE

A thirty-seven-year-old machinist was admitted to the hospital because of sterility.

He had been married for a year and a half. His wife was thirty-nine years old and was said to be normal and fertile. One year before admission two examiners had reported no motile spermatozoa and elsewhere he had been treated with a high-protein diet, thyroid and vitamin E. A third doctor gave him chorionic gonadotropic hormone. He admitted exposure to venereal disease but denied its presence by signs and symptoms. Intercourse was normal. The family history revealed the mother to be living, the father had died of coronary-artery disease. One brother and a sister were married and had children. There was no family history of twins. The patient had a middle-ear infection at the age of one and again at eleven, a mastoidectomy at age seven, circumcision at age thirteen and appendectomy at age thirty-four. At the age of thirty-five he was admitted to the hospital for acute abdominal and back pain. At that time his studies were essentially negative except for narrowing of the joint spaces between the eleventh and twelfth dorsal vertebrae, which were fused, the abnormality being considered congenital. A gastrointestinal series was normal. Examination of the spine was negative. A retrograde pyelogram

was suggestive of stone at the lower end of the left ureter. A bladder culture was negative and the patient was discharged with the diagnosis of acute back strain. In the last two years he had felt logy, and the basal metabolic rate was said to be a "low normal."

Physical examination revealed a normal man of small stature who weighed 150 pounds and was 5 feet, 8 inches in height. The eyes, ears, nose and throat were normal, as were the heart and lungs. Examination of the abdomen was negative. The external genitalia were normal grossly on inspection and palpation. The prostate was normal in size and consistence. The examination of the prostatic secretion revealed no white cells.

The blood pressure was 120 systolic, 80 diastolic. The pulse was 80.

Examinations of the blood and urine were negative. A urine culture was negative. Two semen analyses revealed no spermatozoa. The follicle-stimulating-hormone qualitative test was negative and later positive for 6 mouse units for twenty-four hours. The 17 ketosteroids were 11.2 mg per twenty-four hours and later 10.7 mg.

An attempt was made to catheterize the ejaculatory ducts, and the operator's note was as follows:

The patient had a rather large flat verumontanum. Both ejaculatory ducts were visualized and catheterized for 1 cm. Good seminal vesiculograms could not be made because the dye exuded from the hole which was beyond the amount of catheter inside the ejaculatory duct.

A testicular biopsy was reported as "No diagnostic abnormality recognized." An operation was performed.

DIFFERENTIAL DIAGNOSIS

DR FLETCHER H COLBY: This is obviously a case of male sterility with azoospermia. There are so many factors that come into male sterility that it is difficult to discuss them all. At least we can say that male fertility is a rather delicately balanced affair. It is easily affected by many things, such as the patient's general condition, disturbances of the endocrine glands and temperature changes. A good many years ago Dr Carl Moore, of Chicago, demonstrated the effect of heat on spermatogenesis. The temperature in the scrotum is believed to be lower than that in the inguinal canal or in the abdomen itself. He thought that this was why un-

descended testes have inadequate spermatogenesis Dr Moore's* studies were interesting and carefully controlled. He found that a fertile ram that had an oil silk bag tied over the scrotum soon lost active spermatogenesis. I saw an example of this a few years ago in a male sterility patient who had a small varicocele. In examining this patient I noticed that he wore a suspensory. I asked him how long he had worn it, and he replied three years, night and day. I suggested that instead of having the varicocele removed he take off the suspensory and send in another semen specimen. The first semen specimen showed 20,000,000 sperms per cubic centimeter. The next specimen, one month after the suspensory had been removed, showed 50,000,000, and he reported to me within the next month that his wife was pregnant.

The chief causes for azoospermia are occlusion of the seminal ducts from an inflammatory process, developmental defects, neoplasms of the genital tract and exposure to x-rays. Genital-tract infections as a cause of low fertility have never been adequately evaluated. We have all seen men who have a marked degree of infection in the prostate and seminal vesicle who have no difficulty in getting their wives pregnant. A recent patient with severe genital-tract tuberculosis, impregnated his wife in spite of the infection.

This patient gave no history of infection of the genital tract. The urine was sterile on culture, and the prostatic secretion was normal. Occlusion of the seminal ducts from inflammation, specific or nonspecific in character, was eliminated.

Neoplasms that may affect male fertility are new growths of the testes or spermatic cords or tumors within the prostatic urethra. There was no evidence of neoplasm in this patient. The presence of a papillary tumor of the prostatic urethra that could occlude the ejaculatory ducts may be dismissed by the attempt to catheterize the ejaculatory ducts. Failure to obtain seminal vesiculograms does not necessarily mean any abnormality of the ejaculatory ducts or seminal vesicles.

There is no history of exposure to x-rays.

Thus, we are brought to a defect in development as a cause for the azoospermia. Such a possibility is strengthened somewhat by the fact that a congenital defect of the vertebrae was demonstrated

by x-ray study, and where one congenital defect is present others are likely to exist. The congenital defects that may produce azoospermia are absence of the testes, imperfect testicular descent, imperfect spermatogenesis and congenital abnormalities of the epididymides and vasa deferentia. The testicular biopsy proved that both testes were normal, with active spermatogenesis. We are therefore left with the only remaining possibility—a congenital abnormality between the testes and the ejaculatory ducts. I should suppose the operation performed was to demonstrate this block in the seminal ducts, with the possibility, if conditions were favorable, of performing an epididymovasostomy.

This patient had been subjected to various forms of therapy in an attempt to improve his fertility, and illustrates the value of testicular biopsy in cases of azoospermia before treatment for male sterility is given.

DR ANNE P. FORBES: Would the testicular biopsy be normal with long-standing obstruction due to congenital atresia?

DR TRACY B. MALLORY: Can you answer that, Dr Sniffen?

DR RONALD SNIFFEN: Yes, the biopsy could be normal.

CLINICAL DIAGNOSIS

Congenital absence of vas deferens

DR COLBY'S DIAGNOSIS

Azoospermia due to congenital block in ducts

ANATOMICAL DIAGNOSES

Azoospermia

Congenital absence of vas deferens

PATHOLOGICAL DISCUSSION

DR FRED A. SIMMONS: May I read my operative note?

Under spinal anesthesia a 3.8 cm incision was made in the right scrotum, exposing the testis and epididymis. The testis was grossly normal. The epididymis was normal in the region of the globus major but rapidly thinned out into a fibrous band, and there was no evident globus minor or vas deferens. The spermatic cord was investigated thoroughly in various places, and there was nothing with any resemblance to a vas deferens. In this case fibrous substance appeared into nothing at all, and no trace of a vas deferens could be found. The epididymis was normal in size. A biopsy was taken from the right testis. The same procedure was carried out on the left side.

*Moore, C. R. Physiology of testis and application of male sex hormone. *J Urol* 47:51-44, 1942.

My interest in presenting this case is to bring to the attention of the group the fact that the treatment this patient had before testicular biopsy was unnecessary because he was a normal man with obvious reason for infertility. The simplest way to make a diagnosis of infertility when there is no history of inflammatory disease is to take a biopsy from the testis and examine it microscopically. The specimen need not be any larger than the head of a hatpin. One of these patients, a man of twenty-nine, had perfectly normal testes and living spermatozoa in the epididymides, although he had obstruction.

We had 5 cases with epididymitis on the basis of gonorrhea, all with living spermatozoa in the epididymis. All but 1 had testicular biopsies reported as normal. I do not believe that fact is generally known in the literature, and often patients are deprived of having children.

DR SNIFFEN: In all our cases (about 50) of congenital or acquired defects in the excretory ducts the testicular biopsy has shown active spermatogenesis. One other condition that one might mention in a discussion of azoospermia is the complete absence of germ cells in an otherwise histologically normal testis. The cause of this abnormality is not known. It is apt to be associated with an abnormally high output of pituitary gonadotropins—

CASE 35312

PRESENTATION OF CASE

A seventy-two-year-old Italian man was admitted to the hospital because of a lump over the left breast.

Two years previous to admission the patient noticed a small, freely movable mass, the size of a bean, developing over the left breast just to the right of the nipple. It caused no pain or discomfort but continued growing. The patient denied any loss of weight or appetite.

Physical examination revealed a tumor mass, 6 by 8 by 2.5 cm, located just to the right of the left nipple between the fourth and sixth interspace. It was firm over the lateral part, softer over the medial and cystic in the center. The surface was rather smooth except for a nodule felt over the lateral part. It was adherent to the skin but not to the underlying muscle. The nipple was very slightly retracted, but there were no changes on

the overlying skin. There were no enlarged axillary lymph nodes. Multiple warts were found over the back, and a small sebaceous cyst over the forehead. Examination of the lungs, heart and abdomen was negative.

The blood pressure was 155 systolic, 85 diastolic.

Urinalysis revealed no abnormalities. The hemoglobin was 11.5 gm per 100 cc, and the white-cell count was 9800.

The x-ray examination of the chest revealed fibrocalcific scars in the upper-lung fields. Both upper lobes were reduced in size, and there was a partially calcified, 2-cm lymph node at the right hilus. The left breast was enlarged and was particularly well shown in the lateral projection, in which view there was a suggestion of a small calcium fleck at the base.

On the third hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR RICHARD H. WALLACE: May we see the x-ray films?

DR STANLEY M. WYMAN: The upper-lung fields show dense, fibrotic, partially calcified scars. The upper lobes are reduced in size, and the hili are elevated. There is a suggestion of a lymph node at the right hilus with some calcification within the node. The heart shadow is not remarkable. The aorta is probably calcified. The shadow of the left breast is well seen in the lateral view when viewed in a bright light and can be seen in the posteroanterior projection. The calcification described at its base probably represents calcified costal cartilage, rather than actual calcification in the tumor itself.

DR WALLACE: This is really a rare case when we consider how unusual tumors in the male breast are in general. If one rules out senile mastitis or, better named, senile masoplasia and the enlargement of the male breast that follows hormone therapy, it is really very rare.

Carcinoma of the male breast comprises only about 1 per cent of all breast cancer. In the last 680 cases that Dr Taylor and I reviewed from this hospital, there were only 4 cases of carcinoma of the male breast. However, this series included only cases with radical mastectomy. This particular case was certainly not the usual straight-

forward type of carcinoma — so it probably was something very unusual

It was a tumor of two years' duration, starting as a small, movable, bean-sized mass that increased to the size of 6 by 8 cm, which is a fairly good-sized tumor, as one can see by the x-ray film. One interesting thing is the variation in the consistence of the tumor. It was hard and nodular on one side and soft on the other, with a cystic center, but there is no mention of transillumination, which might have been helpful, especially in the presence of fluid. Transillumination might well have shown the presence of dark, rather than light, clear fluid, which would be helpful. The dark fluid might be blood or old blood or broken-down tumor, which, of course, would influence one a little on deciding whether or not the tumor was malignant.

There was adherence to the skin. I am assuming that this was not inflammatory because of its duration and behavior and the absence of signs of inflammation. A tumor that involves the skin with adherence is practically always malignant. One confusing exception to that is fat necrosis, which can cause the picture that we generally consider characteristic, clinically, of carcinoma of the breast. There was no history of trauma in this case, and I do not believe that a tumor 6 by 8 cm is very likely to have been — or, rather, I just do not believe that it could have been — fat necrosis. The nipple was slightly retracted, and, again, that suggests an invasive tumor. Of course, in the male the ductal portions are more likely to be involved than in the female. There were no palpable axillary nodes. That of course does not necessarily mean that this was benign. Some of the large tumors of the breast are found to be low-grade tumors and do not metastasize to the axilla. If it should be sarcoma, it is extremely rare to have sarcoma of the breast metastasize to the axilla.

It comes down to the question, Was this a malignant tumor or not? Perhaps there is some lead in this history, which to me might be misleading — that is, the sign of old tuberculosis within the chest. Whether or not this calcified fleck is in the tumor or not, as Dr Wyman has said, is not definite by x-ray study. Could this have been tuberculosis with a broken-down area? I think it is extremely unlikely. I am not doing any more than considering the possibility. We do occasionally see calcium in breast tumors, usually as a result

of long-standing tumor with hemorrhage either in the tumor or into a cystic area. It occurs occasionally in the long-standing papillary intraductal tumors that frequently bleed. Sometimes such a tumor will go on for a long time before it changes to become malignant, and old blood, either in the tumor from a small hemorrhage into the tumor or in the fluid, may cause calcification. Occasionally, a low-grade sarcoma of long standing will have areas of calcification. It certainly is an unusual tumor and, to my mind, it comes down to whether or not this was a carcinoma, probably arising in a papillary tumor, a fairly low-grade acinar tumor with degenerative areas or sarcoma of the breast.

DR IRA T NATHANSON. As Dr Wallace pointed out, this is a very unusual type of tumor of the male breast. We have recently reviewed the records of a large number of male patients with breast disease. The large majority of lesions are benign. The physical and histologic characteristics in older men are very much the same as those commonly observed in boys at puberty. In fact, these lesions in the male are akin to the early development of the breast in the female. Clinically, the lesions are represented by firm, well localized, movable and disk-like masses of varying size in the subareolar area. Tenderness is a common feature. There is no evidence of skin attachment or invasion or retraction of the nipple. Histologic appearance is one of an increase and branching of the rudimentary duct systems, with accompanying fibrosis. Alveolar development is rare. The location of these lesions can be easily explained by the fact that the anlage of the breast is immediately beneath the nipple. These lesions in the male may be entirely unilateral or involve both breasts simultaneously or successively. The lesions in contrast to those arising as a result of disease elsewhere,* are considered an integral part of hormonal alterations occurring during puberty or at the climacteric. As a rule these lesions regress spontaneously in both the young and the older males. Diagnosis is usually made without difficulty by those cognizant with the syndrome, and the patients are usually treated conservatively although careful observation is advised. If there is no regression after a reasonable period, excision is advised primarily for psychologic and

*Nathanson I T. Relationship of hormones to diseases of breast. *Surg 16* 108-140 1944

cosmetic reasons in the pubertal male. Cancer must be excluded by exploration in the older male if the process persists even in the absence of definite signs.

A study of almost 100 cases of proved cancer of the breast in the male has revealed that the diagnosis was made with few exceptions at the first examination. These tumors usually arise also in the subareolar area. But, in this case, there is evidence of invasion as manifested by dimpling or adherence to the skin, fixation to deeper structures and retraction of the nipple. This may occur early in the course of the disease since there is less breast tissue and usually less subcutaneous fat in the male. This characteristic may also permit easier accessibility of the tumor to routes of metastases.

Consequently, one would believe, as Dr. Wallace does, that the lesion under discussion was a malignant process because it presented two suggestive earmarks of cancer: skin adherence and retraction of the nipple. The prognosis of cancer in the male breast is less favorable than that in the female. This is probably due to the usually more advanced stage of the disease when the patient is first seen. Tenderness, a common feature of a benign process, is usually absent, and as a result the patient is frequently unconcerned until the diagnostic features of cancer are obvious. To reiterate, the lesion in this patient is rare, for most of the cancers in the male breast are of the more malignant type and invade and ulcerate early.

CLINICAL DIAGNOSIS

Carcinoma of breast?

DR. WALLACE'S DIAGNOSIS

Carcinoma arising in intraductal papilloma

ANATOMICAL DIAGNOSIS

Papillary adenocarcinoma of breast

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The specimen we received showed a partially solid, partially cystic tumor, which evidently had originally been an intraductal adenoma but had become slightly invasive at the periphery and was classified as a papillary adenocarcinoma of low-grade malignancy. It contained a great many flecks of calcium scattered throughout the tumor: small, round, concentric spheres, looking very much like corpora amylacea or the psammoma bodies that one sees in ovarian tumors. That is a distinctly unusual feature, and I do not offhand recall another breast tumor showing it. I believe, in view of various factors in the patient's condition, it was thought not wise to do a radical operation in this case, and a simple mastectomy was done.

DR. NATHANSON: The patient was discussed in the tumor clinic conference. A simple mastectomy was advised because it was thought to be a benign process. Once the final diagnosis became obvious, it was the consensus of the clinic, in conjunction with Dr. Castleman's opinion, that the patient would get by with a simple mastectomy. We would have done a radical resection had we suspected the diagnosis before operation. Do you agree, Dr. Taylor?

DR. GRANTLEY W. TAYLOR: Yes.

THE EPIDEMIOLOGY OF MORALS

TIME was when the public-health officer was verbally if not actually stoned for tacking the red scarlet-fever sign on the door — when the legal diagnosis of contagious disease and enforced quarantine was an un-American invasion of the family's and the family doctor's rights. The country has come a long way. Recently the United States Public Health Service has entered new and wider areas of investigation for instance, community surveys of heart disease and diabetes, and latterly the incidence of marriage and divorce.

All pollsters are to be feared, even those bearing such fascinating gifts as Dr. Kinsey and his colleagues do. One cannot yet picture the hurried census taker or the eager district health worker inquiring after the waxing and waning of the nest-

ing instinct in a harassed housewife at 10 o'clock in the morning. Nevertheless the interest of public-health authorities in the plain, uninterpreted figures on marriage and divorce means a beginning in the epidemiology of morals.

The Federal Security Agency's Public Health Service announces that both marriages and divorces have declined in the last two years, there being one third fewer divorces in 1948 than in the peak year 1946, when 610,000 divorces were granted. In 1948 there were one eighth fewer divorces than in 1947. The decline in divorce rate per 1000 in the three years is 4.3, 3.3 and 2.8. In 1946 there were 2,000,000 marriages, and in 1948 about 500,000 less. Marriage rates per 1000 in these three years were 16.4, 13.9 and 12.4.

There is no cause for encouragement in these figures on the brief postwar span. The heightened sense of so little time during the war doubtless intensified the urge to procreate, the appetite for the fullness of life experience or the search for emotional security in marriage. The special war situation in this respect has passed, and there are those who estimate that one in three marriages may still end in divorce. When statistics are reviewed over several decades,¹ it is found that both marriage and divorce have increased in relative frequency. The figures, moreover, do not indicate the effects of disrupted marriage on the children, the parents or society as a whole.

Most very young women are clear about the future. They plan to marry. As a young lady recently said to her father who was chiding her about a poor school report: "You don't need a diploma to get married." Most young men, it should be admitted, do not know what it is all about when they get married. The question, if not actually popped by the girl, is by pressures or contrivances put in the young man's mouth. In short, if he knows what he is doing, the young man is not in love. Marriages for sex alone soon pall and quickly fall apart. Marriages for children alone, after some years, find the mother without a job when her offspring are grown and in college or off on careers or marriages of their own, while the middle-aged father, aware of his failing powers, looks for a corn-haired sweetie to restore his confidence. How many friends for

whom one stood at the altar twenty-five years ago ask advice now because of a vague sense of cracking up and the windy melancholy, suggesting that one prescribe or approve a change of job, of locality and especially of wife! This was one of the factors that made the forty-five-year-olds so belligerent during the recent war. Contrariwise, not a few of the women approaching middle age, their tubes tied or the uterus removed on some pretext or other, have a sexual eagerness not easily satisfied by their disenchanting husbands. With all its rationalizations, divorce often is really a very banal affair of the glands and other monkey business. Divorce may be cunning or slick or smart, but it is not often intelligent. It is impulsive or instinctive, it may even result from an honest affair of the heart, but not of the educated or understanding heart.

Sigmund Freud² states that the id and the super ego struggle for the ego, which makes an uncertain compromise called neurosis or civilization. On this naturalistic basis there is reason for marriage in that it conserves the libido, the work of the world and human creativeness in this view are mere sublimations. In the gospel according to St Paul, nineteen centuries ago, neurosis was well described and in closely similar terms. "For the flesh lusteth against the spirit and the spirit against the flesh and these are contrary the one to the other so that ye cannot do the things ye would" (*Galatians* 5:17). The basis of this gospel is not naturalistic but is one of values not susceptible to proof by reason alone. The resolution of the neurosis is not by a life-long haggling in the economics of pleasure and pain but by the growing realization of individuality in devotion to another's good. The physiology of these opposite assumptions is identical. The one remains natural, the other adds that which makes man different from animals—the capacity to retain values and to pass them from generation to generation.

In this realm of values, human relations at their hoped-for best, and indeed man's relation to his universe, are represented in terms of family ties. An epidemiology of morals is a welcome barometer for the spiritual climate, apprising one of fair or foul weather ahead. At the moment the glass seems to be still falling in spite of the cheery figures from

the Surgeon General. In these seas the general practitioner is more weathervise. He should consult his own traditions and his best insights and appropriately admonish the voyagers committed to his care.

BRITISH-AMERICAN EXCHANGE FELLOWSHIPS IN CANCER RESEARCH

OF GREAT interest is the recent announcement that the American Cancer Society, in conjunction with the British Empire Cancer Campaign, is offering British-American exchange fellowships in cancer research. The fellowships will provide specialized training for American investigators to study in Great Britain, where there are opportunities for study and research that are not generally available in this country. An equal number of young British scientists will be selected for specialized training in the United States.

The stipends are generous, and the fields of study offered suggest a sound approach to the problem of cancer in human beings. The annual stipend will be £1000 (\$4020), with an allowance of \$600 for travel to the site of the fellowship. The Committee on Growth of the National Research Council and the Empire Cancer Campaign must approve the institution where the applicant chooses to work and the persons under whose guidance he wishes to conduct his research, which should be applicable to problems of neoplastic growth in specialized scientific fields in which there are superior facilities in Great Britain.

The fellowships are open to United States citizens who possess the degree of doctor of medicine, doctor of philosophy or doctor of science, and are intended for young men and women entering a career in clinical medicine or basic research, as well as for more mature candidates who wish to extend their competence in these fields. Applicants must be able to show that they have the qualifications necessary to investigation in the fundamental sciences or in clinical medicine. Applications should contain reference to the institution in which the

COMPLETE ACROMIOCLAVICULAR DISLOCATION

BOARDMAN MARSH BOSWORTH, M D (Oxon)*

BRONXVILLE, NEW YORK

FOR a lesion that appears to be so simple, complete acromioclavicular dislocation can be one of the least satisfactory of traumatic injuries to treat. It is rarely difficult to reduce the dislocation but to *hold* the reduction is another matter.

STRUCTURE AND FUNCTION

This problem is best approached by a brief consideration of the structure and function of the parts involved. In man, the upper extremity is not normally used for weight bearing but largely for prehension and tactile information — uses that require an extreme degree of freedom and as full a range of motion as possible. Such mobility is assured through an anatomic strut, the clavicle, which holds the scapula well out from the central body axis, acting somewhat as the boom of a derrick.¹ At the outer end of this strut the scapula, a relatively large and heavy bone from which the whole upper extremity depends, joins the clavicle through a single small and inherently weak articulation. The average acromioclavicular-joint surfaces measure only 1.9 by 0.9 cm., the capsular ligaments are thin, and the joint is at an added mechanical disadvantage in that, in most cases, the articular surface of the acromion slightly underlies that of the clavicle.

Obviously re-enforcement is needed. It is provided by the dense, strong fibers of the coracoclavicular ligament, which occupy the 1.3-cm. space between the upper surface of the coracoid and the undersurface of the clavicle (Fig. 1). This ligament has no anatomic connection with the acromioclavicular joint, but it is essential to the proper functioning of that joint.¹⁻⁴ It is tough, but elastic and so arranged as to allow a small amount of motion in *all* axes at the joint, it should be noted that this includes some degree of rotation about the long axis of the clavicle.^{1, 5, 6} However, as Codman¹ has emphasized, "All these motions are very slight in degree and the range of the acromioclavicular joint is only the range of the pliability of the coracoclavicular ligaments themselves." Rarely,

the ligament is replaced by a joint,^{7, 9} but this is of academic rather than practical interest.

PATHOLOGY

In essence, the coracoclavicular ligament serves as a short, stout cord by which the scapula hangs from the outer end of the clavicle. If that cord is disrupted (Fig. 2) the acromioclavicular joint will dislocate, the outer end of the clavicle will move up and back, the scapula, with the upper extremity, will drop downward, forward and inward, and the patient will be unable to abduct his arm. This is the picture of complete acromioclavicular dislocation, and it is imperative, when repair is contemplated, that attention be focused not on the dislocated acromioclavicular joint but on the torn coracoclavicular ligament.

Healing takes place here, as elsewhere in the body, by scar formation. If the torn ends of the ligament are maintained in apposition during the six to eight weeks that healing requires, firm re-establishment of ligamentous integrity is the rule. An interesting observation is the frequency with which calcification, and later ossification, occurs within and about the torn ligament.¹⁰⁻¹² Whether this is due to hemorrhage or detachment of periosteum, or both, is a matter of conjecture. Apparently, it is an interesting pathological finding that is unrelated to the type of treatment used and, fortunately, has no adverse effect upon function or cosmesis.¹¹⁻¹³

Partial dislocation of the joint occurs when the capsular ligaments give way with little or no tearing of the coracoclavicular ligament, displacement is usually negligible, and the prognosis, with temporary external support, excellent. However, *complete* dislocation, which involves tearing of the coracoclavicular ligament, is the sole consideration here.

ETIOLOGY

Complete dislocation results from a severe blow impinging upon the acromion in such a way as violently and suddenly to depress it in its relation to the outer end of the clavicle. This occurs in one

*Associate attending surgeon, Grasslands Hospital, Yalballa, and Lawrence Hospital, Bronxville, New York; assistant attending surgeon, Mt. Vernon Hospital, Mt. Vernon, New York.

proposed study is to be conducted, the person under whom the candidate desires to work, the problem to be investigated and the date on which he wishes to begin his research. Appointment to the staff of a university, with teaching duties, is permitted, provided it carries no additional salary and is acceptable to the two organizations sponsoring the fellowships, as well as to the Committee on Growth. Once accepted, the fellowship may not be vacated, nor the place of work changed within the period of tenure without the consent of all three organizations.

Applications may be submitted at any time to the Executive Secretary of the Committee on Growth, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D C.

The fellowships should result in constructive progress in cancer research. It is to be expected that the applicants who benefit from the opportunity offered will also act as ambassadors of good will in the countries of their study.

WELFARE STATE

CONGRESS passed in June a record annual budget for public-health service that provided increases for mental health, cancer and heart research and aid to the various states. In addition a bill was introduced in the House, to which the medical profession certainly will not object, to raise the pay of all physicians, dentists and nurses in the Veterans Administration.

According to the terms of the Federal Security Agency's appropriations bill, 40 medical and 16 dental schools will receive \$872,477 for training in cancer, 31 institutions, including the American Cancer Society and the American College of Surgeons will share \$550,802 in special cancer-control-project grants, and 99 cancer-research projects will receive a total of \$1,026,294.

Congress has further voted \$100,000 for blue prints and specifications for the National Dental Research Institute to be built in Bethesda. (The American Dental Association favored \$2,000,000 to start immediate construction.)

According to the details published in *Washington Report on the Medical Sciences* for June 27,

National Heart Institute received a sizable \$10,725,000 plus contractual authority of \$5,350,000 for research and training grants. To National Cancer Institute went the record sum of \$18,900,000 and, in addition, \$6,000,000 in contractual authority. Another record figure of \$11,612,000 was voted for mental health. And still another, \$12,075,000 to National Institutes of Health, a large part of which will go for research, training, control and fellowship grants in noncategorized fields. Venereal disease activities get \$16,000,000, for general assistance to the states, \$16,600,000 is provided, communicable disease control functions receive \$7,350,000, \$167,000 is allocated for administering the Federal employe health program. For administration of the Hill-Burton hospital program, \$1,200,000 was approved, obviating a drastic reduction in force which would have resulted if the Senate had yielded to the House figure of \$1,000,000.

Without the aid of an adding machine the figures mentioned seem to total \$108,528,573. For no particular reason at all, snatches of a conversation at the Mad Hatter's tea party come to mind.

"And so these three little sisters" — (said the Dormouse) "— they were learning to draw, you know —"

"What did they draw?" said Alice.

"Treacle,*" said the Dormouse.

"But I don't understand" (said Alice), "Where did they draw the treacle from?"

"You can draw water out of a water well," said the Hatter, "so I should think you could draw treacle out of a treacle-well — eh, stupid?"

MASSACHUSETTS MEDICAL SOCIETY

DEATH

KING — Francis B. King, M.D., of Derry, New Hampshire, died on July 10. He was in his forty-sixth year. Dr. King received his degree from Tufts College Medical School in 1934. He was formerly a member of the staffs of Boston City and Boston Psychopathic hospitals and Harper Hospital, Detroit. His widow, a daughter, a son, his mother and a brother survive.

(Notices on page xv)

clavicular dislocation excision of the outer end of the clavicle, fusion of the joint, and restoration of the joint

Excision of the Outer Portion of the Clavicle

In the past few years this has been strongly urged by the late Fraser Gurd¹⁰ for fresh injuries, by Mumford¹⁸ for persistent pain and disability from chronic lesions, and by Urist³⁵ for both. It is not a recent innovation. Removal of a greater or lesser part of the distal clavicle, for this and other lesions, has been practiced for years with acceptable results. Gurd² reported 2 successful cases, Urist³⁵ 9 and Mumford¹⁸ 4, but none of Mumford's patients had complete dislocation. In fact he recommended fascial suture in preference to clavicular excision for this lesion.

Fusion of the Acromioclavicular Joint

In 1943 Caldwell⁴¹ reported 2 cases of chronic complete acromioclavicular dislocation treated by fusion of the acromioclavicular joint with good results at twelve months and five months, respectively. In both patients abduction was limited. No other author has recommended this method in the last ten years.

Restoration of the Acromioclavicular Joint

Restoration of the acromioclavicular joint to its normal anatomic and functional status should constitute the best treatment if it can be accomplished without serious harm or disadvantage to the patient. The difficulty of bringing this about satisfactorily, however, is amply attested by the introduction of the radical procedures just considered as well as by the great variety of reparative techniques described in the literature, all of which fall into one or another of four fundamental groups: skeletal traction, syndesmopexy and ligamentoplasty, wire transfixion-fixation, and screw suspension.

Skeletal traction has few advocates. It may be applied in any one of several ways, but they all involve the very real danger of infection imposed by foreign bodies transfixing the skin for any length of time. This seems sufficient reason to condemn the method, especially since traction can be applied effectively without operation.^{38, 39}

*Syndesmopexy*⁴² and *ligamentoplasty*^{3, 18, 43, 51} may be considered together since they both aim at reapproximation of clavicle and coracoid process by suture material. In the former, foreign substances such as silk, wire and catgut are used, and in the latter autogenous fascia is employed.

Ligamentoplasty, certainly until recent years, has been the method most widely used in the treatment of complete acromioclavicular dislocations. It is subject to numerous modifications. A free graft of fascia lata or the coraco-acromial ligament⁴⁴ or a portion of the short head of the biceps brachii⁴⁵ may be used. These materials may be passed

completely around the clavicle and coracoid or through drill holes in the bones. Reinforcement is usually provided with silk, cotton, catgut or wire sutures. In 1 case a coracoclavicular screw was used to reinforce a repair made with part of the short head of the biceps.⁵²

Twelve good results with this repair have been reported by five different surgeons^{43-46, 48} in the last decade. Serious complications, such as infection and sloughing of the fascia, are not mentioned. However, it is known that they sometimes occur.⁵³ Some surgeons supplement the operative repair with a cast for four to six weeks.^{43, 44}

Wire transfixion-fixation was introduced by Gordon Murray¹³ in 1940 with the report of 5 cases successfully treated with Kirschner wires inserted horizontally through the acromion, across the joint and into the clavicle.

Phemister⁵⁴ prefers heavy threaded wires, which are removed after two months. He immobilizes the arm and forearm for one month and the arm alone for an additional month in a Velpeau bandage. He does not permit shoulder motion while the wires are in place for fear of their breaking. He reports 2 cases with excellent results at four years and five months, respectively.

Bloom⁵⁵ used wire transfixion-fixation in 12 cases in the Navy, with results that were presumed to be good because the men were rated as on active duty three and a half to ten months after the wires were removed.

Screw suspension^{6, 11, 56-59} is, as its name implies, a method of *suspending* the scapula from the clavicle by a vitallium lag screw (Fig. 3) until the torn coracoclavicular ligaments heal. It is *not* fixation.⁶⁰ This procedure accomplishes the effects of syndesmopexy and ligamentoplasty by a relatively simple and minor operation performed through a small incision under local anesthesia.

Certain points in technic are essential to success. The acromioclavicular joint must first be reduced. The hole in the clavicle should be somewhat larger than the screw shaft. The screw must be made to bite its own way into the coracoid, without previous drilling, and it should be set deeply enough firmly to grip both the upper and the lower cortices of the coracoid. Postoperative management includes immediate use of the extremity for all light activities, such as shaving and dressing. All lifting, pulling or pushing must be absolutely prohibited for eight weeks, since during this period the screw alone is depended upon for support.

In 1941 the first 4 cases in which this procedure was carried out were reported.⁶ Later, the method was independently devised by Vere-Hodge⁵⁸ in England, where it was used during the recent war. He has done 7 cases with very satisfactory results at three weeks to four years after operation.¹² Dyer⁵⁶ has reported 4 cases with excellent results at two to six months. Stewart⁵⁷ discussed 9 patients op-

of two ways either an object falls on the acromion or, more commonly, the patient falls and lands on the acromion

DIAGNOSIS

The distinction between partial and complete dislocation is an important one to make, since it affects treatment. The diagnosis of complete disruption is obvious in cases in which the tip of the clavicle lies free and high in the subcutaneous tis-

FIGURE 1 The Coracoclavicular Ligament, a Short, Stout Cord by Which the Scapula Hangs from the Outer End of the Clavicle

sue, tenting and nearly perforating the overlying skin. In other cases the diagnosis may be difficult. The best criterion is roentgenographic evidence of a widening of the space between the coracoid process and the overlying clavicle on the affected side, as compared with the other, normal, shoulder³ (Fig 2). This may easily be demonstrated on a single roentgenogram, taken to include both shoulders, with the patient standing. I have not found it necessary to have the patient hold a heavy weight in each hand,¹⁰ although this might be of assistance in some cases.

TREATMENT

Forms of treatment suggested for complete acromioclavicular dislocation fall into two main groups, operative and nonoperative.

NONOPERATIVE

This is an attempt to maintain reduction by externally applied pressure, or by traction, until healing of the torn coracoclavicular ligament has taken place. A review of the literature of the past decade reveals many methods aimed at accomplishing this result.

The procedures advocated include the following: adhesive (or other) strapping,¹⁴⁻²² a figure-of-8 bandage, as for fractured clavicle,²³ sling and pressure dressing,²⁴⁻²⁵ a "suspension hammock" with a cradle under the axilla,²⁶ a brachioclavicular splint,²⁷⁻²⁹ a thoracobrachial cast with pressure pad,³⁰⁻³⁶ a thoracic cast with axillary crutch³⁷ and abduction traction and suspension in bed.³⁸⁻³⁹

It is extremely difficult to compare results of these different methods for two reasons: careful studies of long-term end results are regrettably scarce, and many authors do not distinguish clearly between partial and complete dislocations.

Urist³⁵ recently presented a four-week follow-up study of 15 complete dislocations in young soldiers treated with the thoracobrachial cast and pressure pad. All were kept in the cast for six weeks and then

FIGURE 2 Rupture of the Coracoclavicular Ligament, Resulting in Complete Acromioclavicular Dislocation

had 2 weeks of physiotherapy. Among the 15 patients, there were 3 redislocations within four weeks, and in 2 of these cases symptoms were severe enough to require subsequent operative intervention. Thus, failure of conservative treatment was appreciable in a small but well controlled series of freshly incurred injuries in young healthy persons—all treated with the same nonoperative method by the same doctor. In an earlier paper Ehler⁴ reported excellent one-year to three-year results in 22 of 26 complete dislocations treated with a sling and pressure dressing. Howard²⁷ observed success in 8 out of 10 complete luxations treated with a brachioclavicular cast. Significant reports of end results obtained by the other conservative methods of treating complete acromioclavicular dislocations are lacking.

OPERATIVE TREATMENT

Three basically different surgical concepts have been followed in the treatment of complete acromio-

simpler operation is to be preferred, if its results are comparable to those of the more radical procedures

There are certain disadvantages inherent in wire transfixion-fixation. The acromioclavicular joint is completely immobilized, with consequent limitation of motion, for eight weeks. Two operations are required, for the wires must be removed. Wires that have migrated from the shoulder have had to be removed from the neck and even from the lung.⁶¹

The method of screw suspension is free of these objections. Mobilization of the upper extremity is assured from the day of operation. In fact, most patients feel so well that it is difficult to keep them from overdoing. In only the exceptional case need the screw ever be removed. I know of no case in which a screw has migrated to another part of the body. The operation is physiologically sound, suspensive reinforcement is provided at the exact point where it is required anatomically and functionally—and without fixation. No important structures are endangered by the screw.

SUMMARY

The various nonoperative and operative methods of treating complete acromioclavicular dislocation are reviewed, and their merits and faults discussed and their end results presented. Screw suspension appears to be the simplest, safest and surest procedure thus far devised for this disabling lesion.

erated on successfully. My first 10 patients have now been followed personally for four months to seven and a half years (Fig 4). In 8 the result is rated as excellent, with no deformity or pain, with a full range of active and passive motion and with normal strength. One patient obtained an excellent result of the acromioclavicular repair but has some limitation of abduction from a surgical-neck fracture

Screw Suspension, which Maintains the Torn Ends of the Acromioclavicular Ligament in Apposition Until Healing Re-establishes Ligamentous Support

on at the acromioclavicular joint is preserved because the hole drilled in the clavicle is larger than the screw shaft

of the humerus on the same side, subsequently incurred. It is interesting to note that, although the later injury was severe enough to fracture this patient's humerus, the acromioclavicular joint did not redislocate. In an early case in which complete reduction had not been obtained at the time of operation the thin screw that was then being used broke at a later date and redislocation occurred. This patient refused reoperation.

An additional 8 cases operated upon by six other surgeons, with follow-up periods of one month to four years, were reported earlier this year.¹¹ Seven of these patients had excellent results, and there was 1 failure. The known end results, therefore, in 38 cases operated upon by ten different surgeons were good in 36, with failure in 2.

DISCUSSION

It must be admitted that satisfactory results are sometimes obtained by nonoperative treatment.^{24-26, 27-28, 29} However, externally applied restrictive dressings are uncomfortable to wear, they require constant supervision and adjustment, they involve a protracted disability and in many

cases operative intervention is eventually required. In my experience, certain nonoperative methods, such as adhesive strapping, Velpeau dressings and figure-of-eight bandaging, are utterly ineffective in maintaining reduction of a complete dislocation and should not be used.

Most experienced clinicians prefer some form of surgical operation in the treatment of this lesion. The specific procedure chosen will vary with the individual experience and prejudices of the surgeon. Excision of the outer portion of the clavicle and fusion of the acromioclavicular joint both seem to me unphysiologic and unnecessarily radical. After excision of the end of the clavicle most patients experience easy fatigue and weakness in the operated shoulder as compared with the normal, and there is a certain amount of displacement of the affected shoulder.²⁵ This is to be expected when the strut-like support of the clavicle is removed. Fusion of the acromioclavicular joint, by completely eliminating joint motion, necessarily interferes with full shoulder function, especially abduction, as has been proved experimentally.⁵

I consider it far better to preserve the acromioclavicular joint and to restore its function by one

FIGURE 4 *Excellent Function More than Seven Years after Screw Suspension for Complete Right Acromioclavicular Dislocation*

The screw is still in place

of the reparative methods described above. Skeletal traction is the least desirable of these, owing to the risk of infection. Syndesmopexy and ligamentoplasty are major operations. They require a general anesthetic, hospitalization for one or two weeks and a prolonged period of disability and rehabilitation. An additional objection to syndesmopexy is that wire or silk sutures tend to cut through living bone by pressure necrosis when subjected to constant strain over a period of time.

One must face the fact that the majority of these injuries are treated by the general surgeon and that most surgeons will see only a few such cases during all their years of practice. Therefore, a technically

simpler operation is to be preferred, if its results are comparable to those of the more radical procedures

There are certain disadvantages inherent in wire transfixion-fixation. The acromioclavicular joint is completely immobilized, with consequent limitation of motion, for eight weeks. Two operations are required, for the wires must be removed. Wires that have migrated from the shoulder have had to be removed from the neck and even from the lung.⁶¹

The method of screw suspension is free of these objections. Mobilization of the upper extremity is assured from the day of operation. In fact, most patients feel so well that it is difficult to keep them from overdoing. In only the exceptional case need the screw ever be removed. I know of no case in which a screw has migrated to another part of the body. The operation is physiologically sound, suspensive reinforcement is provided at the exact point where it is required anatomically and functionally—and without fixation. No important structures are endangered by the screw.

SUMMARY

The various nonoperative and operative methods of treating complete acromioclavicular dislocation are reviewed, and their merits and faults discussed and their end results presented. Screw suspension appears to be the simplest, safest and surest procedure thus far devised for this disabling lesion.

NOCARDIOSIS

Pneumonia and Empyema due to *Nocardia Asteroides*

HERBERT F. HAGER, M.D.,* ANTHONY V. MIGLIACCIO, M.D.,† AND RAYMOND M. YOUNG, PH.D.‡

PROVIDENCE, RHODE ISLAND

IN 1888 Nocard¹ described an acid-fast sporothrix, *Actinomyces farcinicus*, as the cause of *farcies du boeuf*, or bovine farcy. Eppinger,² in 1891, reported an aerobic, gram-positive, acid-fast actinomyces as the etiologic agent in a man dying with cerebral abscesses and meningitis. Since then the species of actinomycetes having acid-fast properties has been known as *Streptothrix eppingeri*, *S. asteroides*, *Oospora asteroides*, *Actinomyces asteroides*, *Nocardia gypsoidea* and more recently *N. asteroides*.

The literature on infections caused by this organism is not voluminous and indicates that cases are not common. The diagnosis in the great majority of cases was made only at autopsy or in the late stages of the illness. Furthermore, in the 37 cases reported, only 6 patients are known with any certainty to have survived. One of these was a case of Madura foot treated by amputation of the extremity.

Henrici and Gardner,³ in 1921, collected 26 cases of acid-fast actinomycetes and added a case. Most of these cases apparently were of pulmonary origin. In the case reported the patient was treated with an antigen made from the cultures. The final results of this treatment are unknown. Goldsworthy,⁴ in 1937, and Kessel and Goolden,⁵ in 1938, reported fatal cases. Benbow, Smith and Grimson,⁶ in 1944, described 2 cases in which surgical drainage, vitamin therapy, roentgen-ray therapy and sulfonamide therapy were used. These were the first reported cases in which the patients are known to have recovered except for the one treated by amputation. In 1945 Binford and Lane⁷ discussed a case diagnosed at autopsy. Kirby and McNaught,⁸ in 1946, added 2 more fatal cases. In 1946 Shaw, Holt and Ray⁹ reported a case successfully treated with penicillin, thymol, potassium iodide, sulfadiazine, and surgical drainage of an empyema cavity. In the same year Calero¹⁰ described a twelve-year-old white girl who was considered cured after therapy with sulfonamides and penicillin, but who at the time of dismissal still had an elevated sedimentation rate.

Glover et al.,¹¹ in 1948, summarized the literature and reported in detail the case of a twenty-six-year-old physician in whom the diagnosis of nocardiosis was established more than two years after the onset of his illness. He was considered successfully treated

by sulfadiazine after penicillin and streptomycin had failed. The authors believed that if the case of Madura foot cured by amputation and the case treated with antigen in which the final outcome was not known were excluded, only 5 of the 37 known cases could be considered clear-cut examples of recovery. They attributed the success in these cases to the administration of sulfadiazine. On the basis of their studies and those of Drake,¹² they doubted whether penicillin or streptomycin was effective in the treatment of this disease.

The first case of *N. asteroides* infection reported below failed to respond to sulfadiazine, penicillin or streptomycin until surgical drainage of an empyema cavity was instituted and until these antibiotics were used in combination and in large doses. This combined therapy apparently resulted in complete recovery, since the patient was free of symptoms and signs twelve months after discontinuance of all therapy. The case is of further interest in that the diagnosis was established early in the course of the illness.

A second case of pulmonary infection presumably due to *Nocardia asteroides* has recently been observed. A detailed report of the case is not presented, but results of the sensitivity tests of the organism to sulfadiazine, penicillin, streptomycin and aureomycin are reported.

CASE REPORT

CASE 1 O. M., a 16-year-old schoolgirl, had been well and active during the year prior to her present illness except for an upper respiratory infection, which had occurred 2 months earlier and which had been diagnosed as influenza. On December 24, 1947, she felt feverish and weak, and had pain in the right lower portion of the chest anteriorly. On the following day, the temperature was 100.6°F, and there was splinting of the respiratory muscles on the right side. Posteriorly, the breath sounds were bronchovesicular and diminished, but no rales could be heard. There was a soft systolic murmur at the fourth left interspace. The patient had two episodes of spontaneous epistaxis. Sulfadiazine therapy with equal amounts of sodium bicarbonate was given. On December 28 the temperature had risen to 102.8°F, and the physical signs suggested further extension of the pulmonary lesion, together with findings of free fluid in the right pleural space. There was a cough, which persisted, but sputum was raised on only one occasion. The patient was admitted to the Rhode Island Hospital, where she remained for the duration of her acute illness.

A roentgenogram of the thorax (Fig. 1) on admission to the hospital revealed the heart to be slightly enlarged, but with a normal contour. The left-lung field and diaphragm were normal. The right-lung field showed an area of diffuse density in the lower half through which the diaphragm could be seen faintly. In the lateral half of the right upper portion of the chest there was a large, localized area of density believed to represent an encapsulated collection of fluid in the pleural space.

*Physician, Outpatient Department, Rhode Island Hospital and Charles V. Chapin Hospital.

†Associate surgeon, Rhode Island Hospital; surgeon, Rhode Island State Infirmary; member consulting staff, Charles V. Chapin Hospital.

‡Research bacteriologist, Institute of Pathology, Rhode Island Hospital.

The urine was normal. Examination of the blood showed a red-cell count of 3,500,000, with a hemoglobin of 11.8 gm, and a white-cell count of 13,850, with 77 per cent neutrophils, 11 per cent lymphocytes and 12 per cent monocytes. The blood urea nitrogen was 9 gm per 100 cc. A blood culture on December 28, 1947, and numerous subsequent cultures were sterile. A sputum culture revealed *Streptococcus viridans* to be the predominating organism. No acid-fast organisms were seen.

In summary, the only abnormal physical findings were those pertaining to the pulmonary lesion and the general febrile reaction. The patient clinically did not appear as ill as would be expected in a pneumococcal pneumonia, and another etiologic agent was suspected.

The patient was given 100,000 units of crystalline penicillin intramuscularly on admission, and 50,000 units every 3 hours. On the 2nd hospital day the temperature was normal but subsequently it rose irregularly each day for the next few weeks. On December 30 aspiration of the pleural space was attempted posteriorly and anteriorly, but only 2 cc of sterile bloody fluid was obtained. On January 6, 1948, a second aspiration high in the axilla in the third interspace resulted in 20 cc of sterile serosanguineous fluid. After each aspiration, 100,000 units of penicillin was instilled. A roentgeno-

gram of streptomycin, totaling 1.8 gm a day, were instituted. The patient continued to have a dry, hacking cough, but her general condition was good despite the prolonged fever. At this time the signs in the axilla had cleared, but there continued to be dullness to percussion and diminished breath sounds posteriorly. On January 20 the temperature rose to 104°F, and roentgenograms (Fig 2) showed a new dense shadow in the right lower portion of the chest posteriorly consistent with encapsulated fluid. There was a smaller loculation of fluid in the upper peripheral portion of the chest. On January 21 a diagnostic thoracentesis was performed, and free-flowing, foul-smelling, pea-green fluid was withdrawn. Smears

FIGURE 1 Roentgenogram of the Chest Taken on Admission in Case 1

gram of the chest on January 6 showed considerable clearing of the density in the lower-right-lung field, and the encapsulated fluid in the right upper portion of the chest was much smaller in amount. A small quantity of fluid was present in the right costophrenic sulcus.

On January 8, the penicillin was discontinued despite the persistence of slight elevations of the temperature to 99.8°F daily. Roentgenograms continued to show clearing of the pneumonic process and lessening of the free fluid. On January 15 the temperature spiked irregularly to higher levels reaching 101°F daily, and penicillin therapy was again instituted. This elevation of temperature was interpreted as being due to the formation of a loculated empyema. The right leaf of the diaphragm was elevated, and the mediastinum was shifted slightly to the left. Penicillin was omitted 4 days later after no improvement, and intramuscular injections

FIGURE 2 Roentgenogram of the Chest Taken on January 21, 1948, in Case 1

and cultures of this fluid revealed a gram-positive, acid-fast, branching, aerobic organism identified as *A. asteroides*, and gram-negative anaerobic fusiform bacteria.

On the same day a rib resection and open drainage of the empyema cavity were performed, and a large rubber tube was left in place. The cavity was narrow and lined by dense fibrous tissue, which obliterated the surrounding pleural space. It had been entered at the lowest point and dependent drainage was obtained. Antibiotic therapy was increased so that 500 mg of streptomycin and 500,000 units of penicillin were given intramuscularly every 6 hours. Sulfadiazine, 6 gm a day, was begun, the dosage later being increased to 9 gm a day. Sodium citrate was used to alkalinize the urine. Potassium iodide was given by mouth, 500 cc of whole blood was given on two occasions.

Sensitivity tests revealed this strain of *A. asteroides* to be inhibited by concentrations of between 0.004 and 0.008 units of penicillin per cubic centimeter, 0.03 and 0.06 units of streptomycin per cubic centimeter, and 0.62 and 1.24 mg of sulfadiazine per 100 cc. The blood levels of sulfadiazine ranged from 7.0 to 17.3 mg per 100 cc. of free sulfadiazine and from 7.3 to 18.8 mg per 100 cc. of total sulfadiazine. No hematuria or toxic effects from the sulfadiazine or penicillin were noted. On the 27th day of streptomycin therapy, the patient complained of slight dizziness, and when she walked with her eyes closed she staggered considerably. This staggering when visual control of balance is eliminated has persisted ever since, although the Romberg test is nega-

tive and there is no disturbance of gait with the eyes open. No loss in auditory sensitivity has been detected. Streptomycin was discontinued immediately on the appearance of toxic signs after a total of 567 gm had been given. On February 25 penicillin, sulfadiazine and potassium iodide were omitted, and no further antibiotic therapy was administered. The patient received a total of 76,600,000 units of penicillin intramuscularly, 10,700,000 units of penicillin intrapleurally and 288 gm of sulfadiazine orally.

After surgical drainage, the temperature fell to normal and remained so. The operative wound remained clean, and the cavity closed rapidly with little drainage. 500,000 units of penicillin was instilled daily as long as the cavity was open. The tube was removed 21 days after the operation. Iron therapy, in addition to the transfusions, was given for the mild hypochromic anemia. The white-cell count at the height of the illness reached 15,000, with 80 per cent neutrophils. After administration of streptomycin the eosinophils rose from 0 to 42 per cent, whereas the white-cell count returned to a normal of 8050. The sedimentation rate remained elevated until 2 weeks after discharge from the hospital but has subsequently been normal. The cultures of the fluid from the empyema cavity became sterile immediately after surgical drainage of the cavity, but acid-fast, branching rods were seen in the fresh smears 9 days later. The roentgeno-

consistently negative for tubercle bacilli but from which *N. asteroides* was isolated as the predominating organism on several occasions. The patient was afebrile during a short period of observation at the Rhode Island Hospital.

This strain of *N. asteroides* was found to be inhibited by concentrations of between 0.015 and 0.03 units of penicillin, 0.12 and 0.24 units of streptomycin and 0.5 and 1.0 unit of

FIGURE 3 Final Roentgenogram of the Chest Taken since Discharge in Case 1

grams of the thorax taken since discharge have shown complete clearing of the pulmonary lesion (Fig 3).

CASE 2 E. H., a 64-year-old woman, entered the hospital with a history of chronic cough of 3 years' duration, attacks of respiratory distress diagnosed as bronchial asthma and episodes of fever associated with pulmonary difficulty. An x-ray film of the thorax revealed (Fig 4) bilateral apical pulmonary lesions. The film was interpreted as showing a moderate amount of fibrotic streaking involving the entire apical portion of the right upper lobe and a number of discrete, calcific deposits in the apex of the left upper lobe. Small calcified nodules were present in the upper portion of the right hilus. No definite cavitation could be made out. The cough was productive of thick, greenish sputum, which was

FIGURE 4 Roentgenogram of the Chest in Case 2

streptomycin per cubic centimeter, but was not inhibited by 60 milligrams of sulfadiazine per 100 cc of medium.

BACTERIOLOGY

The *Nocardia asteroides* organism appears in Ziehl-Neelsen stains of smears made from fresh purulent material as short branching or single rods that are definitely acid fast, however, smears made from the primary culture of the clinical material show partially and irregularly acid-fast elements, and in addition to branching and rod forms there are fine mycelial filaments, some of which fragment into coccoid conidia (Fig 5). With continued transfer on artificial mediums, the organism tends to lose the acid-fast property. This is particularly true when acid alcohol of the Ziehl-Neelsen technic is used to decolorize, however, by the use of a weak solution of sulfuric acid to decolorize, acid-fast elements may be observed in spite of several transfers on artificial mediums. Different strains of the organism show varying degrees of acid fastness, and the cells of old cultures tend to show more irregularity in this regard.

The organisms are gram positive, but, as is true with most gram-positive species, they tend to lose

the property upon aging so that old cultures become gram-negative.

Nocardia asteroides grows well on routine blood-agar and Sabouraud's mediums under aerobic conditions at 37°C. Colonies appear rapidly, within twenty-four to forty-eight hours, under these conditions and show a dry wrinkled growth, which adheres to the surface of the medium (Fig 6). The surface of the colony develops a chalky white appearance, whereas the portion in contact with the medium shows varying degrees of pigmentation, tan to deep orange. In poured plates the organism grows in small star-like colonies, which suggested the species term "asteroides." The pigmentation and morphologic appearance of the colonies vary with the mediums used and the age of the culture, hence the duplication of names appearing in the literature for this species. The usual sodium hydroxide method for concentration of sputum for tuberculosis destroys *N. asteroides* so that animal inoculations and cultures show no growth of the nocardia organism. The weak or semi-acid-fast property may not be noted when routine decolorization of the Ziehl-Neelsen stain is done and the

cellular fibrous tissue, fibrin, neutrophils, lymphocytes, plasma cells and macrophages with branching organisms scattered throughout the tissues.³ The lesions differ from the tuberculous process in that there is no caseation, no epithelioid tubercles and no giant cells. The dispersed mycelia may not show up with the usual hematoxylin and eosin stains but can be demonstrated readily with Gram's stain.

Acid-fast actinomycetes occur naturally in the soil. Gordon and Hagan¹² find no features that would

FIGURE 5 Primary Culture of Smear, Showing *Nocardia asteroides* (Ziehl-Neelsen Stain)

acid alcohol is allowed to remain too long on the smear. These facts may account for the recognition of so few cases.

The tissue lesions caused by *N. asteroides* differ from those in actinomycosis in that clubbed forms are not produced, nor are nodules or "sulfur granules" formed. The typical lesion is an abscess whose center is composed of necrotic material and leukocytes. Surrounding this material there is an area of dense

FIGURE 6 Blood-agar Plate Showing Colonies of *Nocardia asteroides*

serve to distinguish these soil forms from the pathogenic stains. A similar organism was isolated from a normal throat in 1 case.¹³ Rabbits, guinea pigs and other laboratory animals are fairly resistant to infection with strains that cause disease in human beings.

The development of an allergic reaction can be demonstrated in animals after intratesticular injection of an oil suspension of the live organisms and the use of cutaneous tests. Protein extracts of the organisms cause a swollen area with central necrosis. The allergens are thermolabile and appear to be specific with no cross reactions with tuberculin.¹⁴ By using 0.5 cc of a crude extract of unheated, defatted organisms passed through a Berkefeld filter candle, Glover et al.¹¹ demonstrated positive intracutaneous reactions in twenty-four to forty-eight hours in their patient.

DISEASE IN MAN

The great majority of cases reported indicate that the infection usually begins in the lung, or

that a pulmonary metastasis from some other focus occurs early in the disease. The pulmonary lesion may remain quiescent or asymptomatic for some time, since the metastatic blood-borne secondary abscesses are frequently the ones to be noted first or to cause symptoms. The pulmonary lesions frequently extend to the pleuras, giving rise to an empyema that may form chronic draining sinuses to the chest wall. Of the metastatic lesions, brain abscesses have frequently been noted, and have most often been the lesion causing death. In some cases positive blood cultures have been obtained.⁸ Subcutaneous abscesses are frequently encountered, and the skin may be involved. Some of the cases examined at autopsy have revealed multiple miliary abscesses in many of the organs of the body, such as the brain, liver, spleen, kidneys, adrenal glands, intestinal wall, lymph nodes and muscles.

The most frequently encountered symptoms were anorexia, weight loss, weakness and a chronic cough, which as the disease progressed became productive of foul, greenish, purulent sputum. Hemoptysis was rarely encountered, and cavitation was not usual. In some cases, pulmonary signs and symptoms were completely lacking, and the patients came to medical attention because of the neurologic signs of an intracranial abscess or because of abscesses or draining sinuses. The disease is most easily confused with tuberculosis, and when the illness is localized to a chronic pulmonary infection the true diagnosis may not be established for many months. Two cases of peritonitis have followed operations on the esophagus. The patients in the cases reported have been of all ages from an infant twenty-eight days old to elderly people. The division between the sexes has been approximately equal. The pulmonary lesions may occur in any lobe, and there is often early involvement of the peribronchial lymph nodes. A hypochromic anemia was frequently observed to develop as the infection persisted. Some of the patients died within two weeks of the onset of symptoms, whereas in others the infection was active for at least three years. The average duration of the fatal cases was six months. In every case the diagnosis must be made by bacteriologic study, but it should be suspected in all cases of pulmonary lesions in which the tubercle bacillus cannot be demonstrated or when miliary abscesses are encountered.

TREATMENT

The literature is of little value as a guide to treatment. Prior to the use of the antibiotics, the iodides and thymol were the usual agents and no patients survived. The authors of the reports of the few successfully treated cases are not in full agreement concerning the procedure or drug of choice. When possible the sensitivity of the organism at hand should be tested, and the antibiotics that are effective in inhibiting it should be utilized either alone

or in combination. Of the sulfonamides, sulfadiazine or sulfamerazine seems to be the most active and the least likely to cause toxic reactions. When these drugs are utilized the urine should be alkalinized with sodium bicarbonate or sodium citrate. Penicillin in large doses — or by the utilization of some medication such as caronamide to achieve a sufficiently high blood level to inhibit the organism — seems to be the safest drug available. In the case reported by Glover and his associates,¹¹ the organism was not inhibited by 100 units of penicillin per cubic centimeter of medium. Streptomycin in sufficient concentration inhibits the organism in vitro, but the possible toxic effects on the eighth cranial nerve, with permanent impairment of hearing and the equilibrium mechanism, must be fully appreciated, and the danger accepted. This toxicity, it is now realized, may occur early in therapy and even with small or moderate dosage. Whether dihydrostreptomycin hydrochloride or aureomycin is equally effective in vivo against this organism is not known. The second strain isolated by us was inhibited readily by aureomycin in vitro. It is sound surgical practice to remove by surgical drainage or by aspiration any collections of purulent material. Instillation for local action of the antibiotics is believed to be helpful. In any event, it is necessary to observe the patient carefully for several years for a recurrence, for in 1 case⁹ a reactivation of the infection occurred eleven months after all symptoms and signs had abated.

SUMMARY

The pertinent literature in infections with the acid-fast aerobic actinomycetes *Nocardia asteroides* is reviewed. The characteristics of the organism and of the infection in man are given in brief. A case of pulmonary infection complicated by empyema in a sixteen-year-old schoolgirl is presented. This case was apparently successfully treated by surgical drainage and combined therapy with sulfadiazine, penicillin and streptomycin.

A second strain of *N. asteroides* was isolated from the sputum of a sixty-four-year-old woman with bilateral apical pulmonary lesions. This organism by in vitro tests was found to be inhibited by penicillin, streptomycin and aureomycin, but not by sulfadiazine with levels that usually can be attained clinically when adequate dosages of these antibiotics are administered.

Failure to recognize *N. asteroides* as the etiologic agent in certain infections may account for the scarcity of cases reported. Such failure may be due to the way in which routine specimens of sputum are prepared for inoculation or examination. It is stressed that large doses of the antibiotics to which the organism is sensitive may have to be given and that it may be necessary to administer combinations of two or more in order to obtain prompt inhibition of the organism. Surgical drainage or as-

piration of loculated collections of pus is believed advisable for early healing. Observation for a period of years after apparent arrest of the condition is advisable.

BOSTON

SINCE the elucidation by Chen and Schmidt¹ (1923) of the chemical structure and the pharmacologic effects of ephedrine, this drug has ranked with epinephrine as one of the most valuable medications for the treatment of bronchial asthma. Although less active as a bronchodilator than epinephrine, ephedrine is effective, and its action is prolonged. However, undesirable effects such as nervousness, tremulousness, sleeplessness, vertigo, sweating, anorexia, nausea and palpitation often interfere with the use of the drug or require the additional administration of sedatives. In the last few years, therefore, attempts have been made to produce sympathomimetic compounds with less effect on the cardiovascular and central nervous systems. One of these, orthoxine,|| orthomethoxy- β -phenylisopropyl methylamine hydrochloride (Fig. 1), appears to have certain advantages over ephedrine.

In animal experiments orthoxine was found to be more effective than ephedrine in relieving bronchial spasm induced by histamine, pilocarpine and acetylcholine.^{2,3} It caused practically no pressor response

and less stimulation of the central nervous system than ephedrine.⁴ In man, orthoxine has furnished protection against asthma-like attacks induced with histamine or methacholine.^{5,6}

MATERIALS AND METHODS

Fifty patients with bronchial asthma, about equally distributed between the sexes and ranging in

FIGURE 1 Chemical Structure of Orthoxine

age from four to sixty-three years (the majority being adults), served as subjects for this study. The perennial type of asthma predominated. Some patients were receiving treatment with specific allergenic extracts, and many of them had been instructed to eliminate offending allergens. All subjects were having mild to severe asthma at the time treatment with orthoxine was started, and they were observed for a period of weeks to several months. The dose varied from 50 mg. in children to

100 or 200 mg in adults, given every four hours as needed. Control studies with placebos were used in some cases, and no benefit was observed. Relief of symptoms, when it occurred, was evident in twenty to thirty minutes. The results were classified as follows: excellent, if complete relief of symptoms occurred for several hours; fair, if relief was 50 per cent or more and lasted two or more hours; and unsatisfactory, if the relief was less than 50 per cent or if the duration of activity was short.

RESULTS

As shown in Table 1, 18 (36 per cent) patients had excellent relief, 17 (34 per cent) obtained fair relief, and the remaining 15 (30 per cent) had unsatisfactory results. On the basis of the degree of asthma, patients with mild asthma fared best, followed by

TABLE 1 *Therapeutic Response to Orthoxine*

DEGREE OF ASTHMA	NO OF CASES	EXCELLENT RELIEF	FAIR RELIEF	UNSATISFACTORY RELIEF
		NO OF CASES	NO OF CASES	NO OF CASES
Mild	14	7	6	1
Moderate	21	10	7	7
Severe	15	1	4	7
Totals	50	18	17	15

those with cases of moderate severity. Those with severe asthma obtained the least relief.

Prior to the administration of orthoxine 28 patients had been taking ephedrine in one form or another or, having previously taken orthoxine, had substituted ephedrine. In this way we were able to gather some impression of the relative value of the two drugs, taking into account the degree of relief as well as the intensity of side reactions, discussed in detail below. Ten patients preferred orthoxine to ephedrine. In 2 there was no advantage in one drug over the other, whereas the remaining 16 preferred ephedrine to orthoxine.

In 4 patients, substitution of orthoxine for ephedrine was advantageous. Marked side effects with ephedrine developed in 3, and 1 of these had hypertension. In this patient and in a fourth, who had a recent coronary infarct, it was believed that ephedrine, because of its pressor effects, should not be given. All 4 of these patients tolerated orthoxine well and obtained excellent relief.

Observations were made in asthmatic subjects to determine the degree to which orthoxine could protect against asthma-like attacks and a fall in vital capacity following the inhalation of aerosolized allergenic extracts.⁷⁻⁹ Three patients, all of whom had been tested in this manner and had had significant pulmonary reactions following inhalations of nebulized extracts (5 per cent birch pollen in 2 cases and 0.25 per cent Endo house dust in the remaining one) were chosen for this study. In brief, the patients came to the laboratory when free of asthma and in a

fasting state. Three or four control vital capacities were recorded, after which 200 mg of orthoxine was given by mouth. At the end of an hour the subjects were again tested with the nebulized extracts that had previously caused significant reductions in vital capacity. In no case did orthoxine protect the patients, the pulmonary response being almost identical with that experienced without the drug. Although this technic has been valuable in assaying drugs given parenterally or by inhalation,^{8, 10} administration of drugs by mouth has not given clear inhibition of asthma-like attacks induced with aerosolized allergenic extracts. This may be due to the lack of refinement of the method or to the relatively heavy exposure of the inhaled extract, which may mask slight or moderate activity of the drug. The lack of protection by orthoxine is of doubtful significance and is in contrast to the reported efficacy of this agent given by mouth in affording some degree of protection or relief in asthma-like attacks induced with histamine or methacholine given parenterally.⁶

SIDE EFFECTS

Of the 50 subjects with asthma, 43 (86 per cent) were completely free from unpleasant side reactions. Of the remaining 7 (14 per cent), 4 had gastric disturbances as follows: questionable nausea in 2, nausea in 1, and nausea and vomiting in 1. The last patient was an eleven-year-old boy in whom the same symptoms likewise developed after the taking of ephedrine. Of the other 3 cases, 1 patient had menstrual-like cramps, 1 reported dizziness and sleeplessness, and 1 excessive perspiration. Four of these 7 patients with side reactions obtained little or no relief from orthoxine, so that the drug was discontinued. The remaining 3 had excellent or fair relief of asthma upon decrease in the dose of the drug to 50 mg, or, as in 1 case, when the drug had been withheld for a few days and was again given.

DISCUSSION

The difficulty of judging the effectiveness of an oral preparation for use in bronchial asthma is recognized. Patients have a tendency to overestimate the benefits of any new drug when it is first used. Nevertheless, we believe that our impression of orthoxine is fairly well founded.

The response of 27 out of 35 patients with mild or moderate asthma was excellent or fair with orthoxine, which compares favorably with other well known oral sympathomimetic agents. Similar results with orthoxine were recently reported by Wittich.¹¹ However, the majority of our patients in whom comparison was possible, preferred ephedrine to orthoxine. In the 15 patients with severe asthma, the drug was relatively ineffective. In most cases, these patients obtained relief with other medications such as epinephrine, isuprel and aminophyllin. Our experience is not entirely in accord with the findings of

Curry, Fuchs and Leard,⁶ who, in their clinical studies on 21 asthmatic subjects, observed orthoxine, in doses of 200 mg, to be comparable to ephedrine in 30-mg doses. This discrepancy may be accounted for, in part, by the fact that we often used smaller doses of orthoxine and usually gave ephedrine with a barbiturate.

We are aware that results similar to those obtained with orthoxine might have been obtained with other preparations for asthma. However, the figures cited in Table 1 do not indicate the true value of a preparation such as orthoxine because they leave out of account reactions of individual patients. For instance, more patients may obtain relief from asthma with ephedrine than with orthoxine, as in the cases discussed above but in certain patients who may be unable to tolerate ephedrine, orthoxine may give relief and may be well tolerated. We believe, therefore, that orthoxine is a valuable addition to the list of agents available for the treatment of asthma.

SUMMARY

Fifty patients with bronchial asthma were treated with orthoxine-orthomethoxy- β -phenylisopropyl methylamine hydrochloride. The drug is an effective oral sympathomimetic agent especially applicable to the milder cases of asthma.

Although it did not appear to be quite as effective as ephedrine, orthoxine had the advantage of causing less disturbance of the cardiovascular and central nervous systems. It is concluded that orthoxine is a distinct contribution to the management of bronchial asthma.

CLINICAL OBSERVATIONS CONCERNING SCHIZOPHRENIC PATIENTS TREATED BY PREFRONTAL LEUKOTOMY*

JAY L. HOFFMAN, M.D.†

BEDFORD, MASSACHUSETTS

IT IS my purpose here to consider the clinical results of leukotomy in 42 patients treated by psychosurgery‡ at a Veterans Administration hospital during a two-year period — 1947 and 1948. To prepare for this I have reviewed the clinical records of these 42 patients and, within the past two weeks, have examined those who remained in the hospital. I have also gone over the social-service reports of the patients who have left the hospital and, in a few cases, have interviewed the relatives myself.

I am less concerned in this report with statistics than I am with the qualitative results following leukotomy. Therefore, the only figures that I will give are as follows: of the 42 patients operated on 4 (9 per cent) are now dead§, 14 (33 per cent) are

out of the hospital — either discharged or on extended trial visit, 16 (38 per cent) are still in the hospital, although so far as behavior is concerned they could live at home equally well, and 8 (19 per cent) are still in the hospital and require hospital care because of continuing episodic disturbed behavior.

The evaluation of the results after prefrontal leukotomy will be greatly influenced by the frame of reference one uses. If the condition of the patient is compared with his condition prior to the onset of his psychosis, all the results must be considered failures, for the adjustment of none of the patients — when viewed with true objectivity — compares favorably with the prepsychotic status. If the clinical status after leukotomy is compared with the condition of the patient during the period of his psychosis, practically all the patients, who have survived will be found to show successful results. From the quantitative viewpoint none of the patients, after

‡All patients in this series were treated by the standard operation of Freeman and Watts. Dr. John S. Hodgson was the neurosurgeon.

§Of this number only 2 deaths were directly attributable to intracranial complications of the surgical procedure.

leukotomy, manifest the extreme of unacceptable behavior found before the operation •

The evaluation of this procedure is made uniquely difficult and rather arbitrary by another factor, and that is that the one most directly concerned with the treatment — the patient — has not participated actively in the evaluation of the results. The opinions of the relatives and of the doctors and the nursing staff concerning this procedure are known, but I must confess that the opinion of the patient himself is not known. For, in practically every case, the patient, when questioned, professes not to know anything about any surgical procedure to which he has recently been subjected. This is particularly true when the patient, postoperatively, shows a great deal of dullness, indifference and apathy. Patients who do recognize, as indicated by their replies to questions, that an operative procedure has been carried out on the brain seem to have little or no understanding of the operation or the results to be attributed to it.

Before proceeding farther I wish to make note of the fact that the group of patients under consideration were, with 1 exception, schizophrenics whose illness and hospitalization was of two to twenty years' duration at the time of operation. The results may therefore not be directly comparable with the series of results reported for nonschizophrenic patients, or for schizophrenic patients whose illness has been of relatively brief duration.

Those who have participated in the selection of these patients for leukotomy, or who have had them under care before the operation, are familiar with the preoperative clinical picture. There are no significant exceptions in any of the 42 patients so far as the characteristics mentioned below are concerned. For those who are not familiar with their preoperative clinical picture I may say that, with one exception, they have all been schizophrenics hospitalized for two years or more — generally five years or more. The male patients, for the greatest part, were resident in the building for the most disturbed patients. They were, before operation, excited, assaultive, combative and destructive. Most were hallucinated and deluded and, characteristically, appeared to be tortured, agonized and distressed beyond measure by their morbid mental experiences. Most had made one or more suicidal attempts, and most had required, for greater or shorter periods, mechanical restraint, chemical restraint or seclusion. With but 1 or 2 exceptions, their previous treatment had included convulsive therapy or insulin-shock therapy or both. Most had not been outside a mental hospital for two years, five years or — in 1 case — about twenty years. Their children had forgotten them. Their wives and parents had, in many cases, adjusted their lives so as not to include the patient in their present or future reckonings. By all criteria that are now

known, the future for these patients offered only a continuation of the recent past.

This, then, is a composite clinical picture of the patients in the series before operation. Regarding the postoperative results I wish first to consider the group of patients who are still in the hospital.

Taking one of this group in whom the result is rather more favorable than most, I will arbitrarily select the order and emphasis to be given to the clinical features in the case. This patient is now neat in personal appearance and tidy, eating and sleeping well. The reports of the nurses indicate that, at various times, he attends dances, goes swimming, listens to music, views television shows, goes bowling, reads and visits the occupational-therapy shops. He works on the hospital chicken farm, where he gathers eggs, feeds and waters chickens and cleans the chicken house. When interviewed by me, he stated that he felt relaxed and was no longer hallucinated or delusional, he recalled, without much show of concern, his rather prolonged stay, before his operation, on a ward for disturbed patients. He remembered that it was noisy there and that he could not read. He is polite in his manner today, and answers questions promptly but slowly. He is correctly oriented. He has ground privileges. In response to leading questions he tells me that he was operated on in Ward 2-E. "They call it lobotomy. It means cutting the nerves in my head. I woke up and had a bandage on my head. No, I don't see much difference in the way I feel."

To a greater or lesser extent the clinical results described above are to be found in about two thirds of the group of patients remaining in the hospital. If still hallucinated, they are no longer disturbed by these hallucinations. They no longer require restraint or seclusion. They either have ground privileges, go home on short visits, or are able to live in the hospital under conditions involving relatively little supervision. They participate in the activities — movies, dancing, bowling and so forth — that give most people pleasure. Whether these activities give pleasure to the patients under discussion is difficult to determine. For these patients are not only no longer distressed by their mental conflicts but also seem to have little capacity for any emotional experiences — pleasurable or otherwise. They are described by the nurses and the doctors, over and over, as dull, apathetic, listless, without drive or initiative, flat, lethargic, placid and unconcerned, childlike, docile, needing pushing, passive, lacking in spontaneity, without aim or purpose, preoccupied and dependent.

In the evaluation of these results, with what is one to be most impressed — with the contrast between the tormented, assaultive, maniac and the placid, docile, childlike person who goes to dances, reads, listens to music and goes to the movies? This contrast is indeed both marked and

impressive. However, I cannot but recall the remark of the relative of a patient, as reported in an English journal, that the patient seemed to have lost his soul in the process of being changed from one state to the other. I am further reminded of the story about the farmer who made a pact with the devil. Here, however, it is the surgeon, rather than the patient, who appears to have made the pact, and, unfortunately, there is no Daniel Webster to release the patient from his pact.

I should like to consider the patients who have left the hospital and examine more closely the types of adjustment that, in the records, are reported as "satisfactory." These cases are as follows:

M. G. has been home for 1 year and 9 months. During this period he has been married, and his mother reports that he and his wife are very happy together. She further states that if people did not know that the patient had been in a mental hospital they could not tell it by seeing him or talking to him now. The patient, a musician with some talent before the onset of his psychosis, accepted equably, upon his release from the hospital, his rejection as a student by a music school. The school believed that he had not had enough practice in recent years to be able to profit by further intensive training. He went instead to a school of optics and completed the course in a year. There was no job in optical work readily available, and he did not persist in efforts to find employment in his new trade. Instead he got temporary work in the post office. At present he is going to an upholstery school and has been promised a job by his brother, who owns an upholstery shop.

I. R. has been at home continuously for exactly 2 years. His wife, who remained faithful to him throughout the long period of his psychotic illness and visited him regularly in good weather and bad, whether abused by the patient or not, has bought a house with the accumulated retirement pay of the patient as a down payment. She has remodeled the house so that she collects rent for half of it, and this, in addition to retirement pay, is their only source of income. The patient spent 6 to 8 months at the time of release from the hospital at the Boston Community Work Shop, but it was reported that he was unable to learn any trade. The social-service workers have found several jobs for him, which he either refuses or loses before he starts because he insists on informing his prospective employer that he has had half his brain cut out, that he has been in insane asylums for several years, that he is legally incompetent and that his wife holds all his money. He insists on telling obscene jokes in the presence of strangers and in using profanity freely. Last summer, at a local beach, he distressed a woman neighbor because he calmly placed himself in a conspicuous place on the beach where he unabashedly viewed the charms of the women passing by on the boardwalk overhead. The patient's wife calmed the irate neighbor by telling her that her husband did the same thing, except that he did it furtively. According to the wife, the patient has built a picket fence around their property and puts up shelves and builds bookcases around the house. Objective reports are, however, less favorable and indicate that he is slow at any work he undertakes, that his results are poor, that he does not appear to have a care in the world and that nothing seems to bother him. He shows no sense of responsibility and no sense of urgency to assume the role of father and husband. The opinion of the wife concerning the operative procedure is of interest. I asked her whether, if she had it to do over again, she would again give permission for the operation. Her response came without a moment's hesitation and carried with it a note of conviction: "Yes, indeed. Now we have a home together and are a family again."

Another patient, a woman, has been home for 6 months. Still delusional, but not aggressive about her delusions, she is a slovenly housekeeper, with no sense of responsibility to her husband and children. It is only because her husband is a mild, passive man, willing and able to arrange his working

hours so that he can be home much of the day, that she can continue to live outside the hospital.

F. F. has continued to live outside the hospital, but the circumstances under which this has been made possible are significant. Immediately after the operation, his stepmother was hostile to any plans to bring him home, but an aunt agreed to take him in. He was reported as being friendly and cooperative, but without much drive. Like many of these patients, he was described as being "inconsiderate." By this term, it was meant that he left the water running in the bathroom, neglected to close the outer door on cold days and left the radio blaring for hours on end. After a few months of such behavior at his aunt's home it began to appear that his further stay there would not be welcome. About this time he married a girl he had met since his leukotomy. From the fact that his wife is reported to have had a harelip, one would assume that she would be more tolerant than the aunt of one so handicapped as the patient. This has proved to be the case, and in spite of the fact that the patient continues to be unable to hold a job and to be generally irresponsible, he and his wife appear to be happy and contented.

L. F. lives on the farm of his overprotective mother. While he was in the hospital, his mother used to visit me frequently—pleading, cajoling and demanding to take her son home. Now he is her little boy again. He does simple errands, enjoys playing with boys of 7 and 8 years old in the neighborhood, and is himself shy, childish and dependent. He cannot learn to do any but the very simple chores about the farm. His mother, however, is entirely satisfied.

From the report of another patient it is noted that his mother does not care if he never goes to work again because, as she puts it, she is willing to support him for the rest of his life.

Another continues unemployed after 5 months but is otherwise well adjusted at home. Still another lives with an easy-going mother of limited intelligence. The family are pleased to have him home. He goes to the movies but is otherwise without initiative, and is poorly oriented and mildly confused. His mother writes, "He is no good for any job that would pay money."

Another patient helps his brother in his grocery store by sweeping floors and stocking shelves but is not permitted to wait on the customers.

DISCUSSION

It might be desirable to mention a few minor points concerning which interest has been expressed. Since leukotomy may have, as one of its effects, the reduction of inhibition on the part of the patient, the question of postoperative sexual behavior has been raised. From the information derived from this group of patients it appears that there has been no aggressive or objectionable sexual behavior in any of the patients. There have been open masturbation, preoccupation with obscene jokes, and obscene speech and uninhibited staring at female passers-by. One or two female personnel in the hospital have reported being "annoyed" by these patients, without detailing the type of annoyance, but when the patient was spoken to by his physician there was no repetition. The wife of a patient reports that his sexual interests in her are diverted if she simply turns him over in bed so that he faces the wall.

Some of these patients are extravagant with money and seem to have little sense of value. Others are not. Some are extravagant at first but later learn to take care of money.

The inability of patients to learn to carry out any but the most simple tasks, is noted repeatedly by hospital workers. This fact has considerable bearing on the difficulties the patients have in finding and holding employment.

The point about this study that has impressed me most is that not one of 42 patients has been able to make a fully independent social and economic adjustment after operation. None are completely self-supporting. All require a protective environment—either in the hospital or at home—for survival. All have had to borrow something from the ego of a devoted wife, son, mother or sister. These patients as a group remind me of a watch that has stopped. If one shakes it vigorously the watch is apt to tick a few times, and the tick sounds like that of a watch in good repair, but it runs down almost immediately and stops. In fact, I have not been able to wind these patients up sufficiently so that they can run like an eight-day clock, or for that matter, even for a day.

I recognize that in this brief presentation, I have not discussed the contributions and limitations of medical rehabilitation and social-service activities. Important as these topics are, the limited time at my disposal makes such neglect necessary.

In this presentation I have deliberately described at some length what must be considered the less desirable clinical results of leukotomy. I have done

this because most people interested in the subject have been so impressed by the dramatic changes in behavior produced by leukotomy—from a wildly excited, assaultive, combative, suicidal psychotic to a mild-mannered, docile, “well behaved” patient—that they have, perhaps, overlooked the very real and permanent losses to the integrity of the personality. I think it should be re-emphasized that by psychosurgery an organic brain-defect syndrome has been substituted for the psychosis, but the psychosis has not been cured. Psychosurgery, in my opinion, is a temporary therapeutic expedient, justifiable only because knowledge of specific therapy is still not sufficiently developed or available to effect true cures in many of these patients.

It seems to me that one should be hesitant in recommending leukotomy for the chronic schizophrenic patient unless he is chronically assaultive, combative, homicidal or suicidal and his very life is jeopardized by an uninterrupted continuation of this state, or, in selected cases, the return of the psychotic patient to the family circle of a distraught mother or other relative can be justified for humane reasons. The emotional need of such a mother for her son—morbid though it be—can be satisfied after leukotomy of the son, as I have indicated in some of the cases discussed above.

MEDICAL PROGRESS

EXFOLIATIVE CYTOLOGY*

HOWARD ULFELDER, M D †

BOSTON

THE past eight years have witnessed widespread revival of the study of body fluids as an adjunct in the detection of cancer. The focus of attention in these fluids has been on the cellular constituents—the cells that have become separated from body surfaces by the natural process of desquamation. An apt phrase, “exfoliative cytology,” has been coined by Papanicolaou to describe this field of investigation. It is eminently fitting that he should be the one to do so, for Papanicolaou’s original painstaking observations are the firm foundation on which this science has been built.

Sporadic attempts to use exfoliated cells as an indication of underlying disease have been reported in the medical literature of the last hundred years.

The results were confusing and of low accuracy. Then, in 1917, Stockard and Papanicolaou¹ described the first of a long series of observations on the cellular pattern of aspirated vaginal fluid of rodents. The course pursued in these studies and their culmination in the recognition of cells from malignant growths in the human female genital tract is outlined in Papanicolaou’s² review of 1946. From his reports, one conclusion is inescapable and crystal-clear: a high degree of accuracy in the interpretation of exfoliative cytologic preparations is possible only after one is *thoroughly familiar* with the numerous cellular variations that may be found in benign states.

The number of scientific papers on this subject shows a steady increase every month and proper evaluation of each contribution becomes more and more difficult. It may be helpful to epitomize the procedure in outline form in its simplest terms and

*Presented under the title ‘Evaluation of the Papanicolaou Technique in the Diagnosis of Malignant Disease’ at the annual meeting of the Massachusetts Medical Society, Worcester, May 24, 1949.

to measure each new report in the light of whatever feature it emphasizes

- 1 Preparation
 - a Collection
 - b Fixation
 - c Staining
- 2 Interpretation

Thus there are two basic steps in any cytologic study—the preparation of a slide and its interpretation. Preparation involves collection of material, fixation and staining. Whatever the method of collection, it must have as its goal the transfer to a glass slide of a representative specimen of cells well preserved and recently shed from the area under investigation. The process of fixation should be able to maintain cellular detail for an indefinite period without destroying or removing an appreciable number of the cells originally present on the slide. Staining and counterstaining should provide sufficient contrast to bring out minute nuclear and cytoplasmic morphology, again without destroying or removing cells in the process.

Interpretation, the second basic step, should be restricted to persons who have received special training for that purpose and who are in a position to improve their accuracy by constant practice. Facility in the recognition of abnormal cells can be developed in no other way, the occasional microscopist cannot hope to do so. With this outline and these fundamental principles in mind, some of the literature on exfoliative cytology is reviewed. This is best done if the body systems are considered separately.

FEMALE GENITAL TRACT

Although a brief note in 1928³ has recorded Papanicolaou's earliest conviction that cancer of the uterus sheds recognizable cells into the vaginal fluid, it was not until 1941 that Papanicolaou and Traut⁴ made a complete report, including both the description of their technic and criteria used in diagnosis. A monograph published in 1943⁵ presents their material in detail. Within a few years Meigs,⁶ in Boston, Jones,⁷ in New York, and Ayre,⁸ in Montreal, reported extensive trial of the method and complete agreement with Papanicolaou's conclusions. These early papers are concerned almost exclusively with the problem of interpretation. All agree that the more experienced the cytologist and the more smears examined on a given patient, the greater the likelihood of finding cancer when it is present. Their cytologic accuracy ranged around 90 per cent for patients with carcinoma of the cervix and between 80 and 90 per cent for cases of carcinoma of the fundus. They pointed out that errors of another type were also encountered, when cytologic reports of malignant lesions that could not be confirmed pathologically were rendered. A number of other clinics⁹⁻¹¹ have now studied the

method and reported their results, no one who has given it an honest trial has condemned it. It should be noted that there is considerable variation in methods of statistical analysis, for some papers list cytologic data and calculate percentages of pathological confirmation, whereas others report cases proved to be cancer and calculate percentages of cytologic accuracy. The Vincent Memorial Hospital group uses only the first cytologic report on each patient in its statistics—a method designed to permit evaluation of exfoliative cytology as a screening procedure.

Almost every publication in this field has included cases in which malignant cells were found in the vaginal fluid and the lesion has proved to be pre-invasive cancer of the cervix (carcinoma-in-situ). This fact is of vital importance and, fortunately, is not dependent on mere chance for a comparison. Between smear and biopsy¹² in a group of 181 proved cases of cervical cancer has demonstrated that each of these methods tends to pick up the lesions that the other one misses. Thus, the smear is of great value in revealing extremely early cancer of the cervix, and in this series, by the use of *both* methods of diagnosis, only 3 of the cases were missed at the time of *first* examination.

The interpretation of the vaginal smear after radiation therapy to the genital tract is a special study in itself. The cellular changes noted under these conditions are described by Graham.¹³ These effects are present in both the normal and the malignant cells. When cases were classified according to degree of radiation response as judged by these cytologic changes, remarkable correlation with their clinical behavior was apparent. Graham concluded that the smear may be of great prognostic value in cases of cancer of the cervix treated by radiation.

It is obvious from Graham's paper that a trained observer can, without great difficulty, recognize malignant cells after radiation or other therapy. Repeated cytologic check on such patients may lead to the discovery of persistent or recurrent disease. Over 10 per cent of Meigs's¹⁴ 1015 cases were patients in the gynecologic tumor follow-up clinic, and one of his protocols describes a case in which smears were consistently positive for nine months before recurrent disease of the cervix could be histologically confirmed.

Failure to achieve 100 per cent accuracy has inevitably led to modifications in the method of preparation of the cytologic specimen. As early as 1943 Papanicolaou and Marchetti¹⁵ described the use of a small cannula to aspirate fluid directly from the endocervix and the endometrial cavity. Ayre¹⁶ also has preferred to collect his material from the region of the external cervical os originally by aspiration and more recently by rotatory scraping with a special wooden spatula. This he calls, quite rightly, a "surface biopsy." Hunter¹⁰ has used the Papanicolaou

technic but also collects surplus vaginal fluid in fixative and sections and stains the resulting pellet in orthodox pathological fashion. Each method of preparation produces its own characteristic cytologic pattern, and each demands experience before accuracy is possible.

There is universal agreement that smears should be fixed *immediately* and not allowed to dry. Ether and alcohol, alcohol alone, Schaudin's solution and others have been used with equal success. Staining is usually by Papanicolaou's¹⁷ method, although some prefer hematoxylin and eosin.

Although the exponents of exfoliative cytology point out repeatedly wherein it deviates from the ideal, it is from the pathologist that one expects constructive criticism. Several articles and a handbook of diagnosis by Gates and Warren¹⁸ and their associates present the attitude of the practicing pathologist. They warn against its use in place of other well established methods of diagnosis and decry any complacency founded on cytologic reports alone. In evaluating its use as a screening test for women without symptoms,¹⁹ they question whether the low yield is economically justified. However, they agree that some cases of cancer are unquestionably discovered earlier by this means than would otherwise be possible, and they point out that these investigations have given desirable impetus to the study of very early cancer.

The dramatic possibilities inherent in the cytologic method have not failed to rouse the interest of writers who attempt to interpret things medical for the public at large. At least two articles^{20, 21} have appeared in women's magazines. The facts presented are scrupulously accurate, but their selection and accompanying text are so uncritical that one is left with the impression that any physician who cannot or will not perform this simple test on his patient is derelict in his duty. Such publicity, unfortunately, creates resentment within the ranks of the medical profession and a bias that will have to be overcome by complete honesty of reporting in professional journals.

PULMONARY TRACT

In 1946 Herbut and Clerf²² reported a series of 30 patients with proved carcinoma of the lung in whom bronchoscopic aspirations or washings were studied by Papanicolaou's technic of fixation and staining. In 22 cases (73 per cent) malignant cells were found. Similar study of expectorated sputum in 7 cases revealed cells only once. No false-positive reports are recorded, but the authors draw attention to 7 cases in which cytologic examination showed cancer although bronchoscopy had failed to reveal a tumor. A more recent summary of Herbut's work shows 105 positive smears in 118 cases of cancer of the lung, an accuracy of 89 per cent. A false-positive report was made in 4 additional cases.

Others have not found the examination of sputum so unrewarding. Papanicolaou²³ noted malignant cells in the sputum of 88 per cent of 25 patients with cancer of the lung, and Woolner²⁴ states that sputum or bronchial secretion proved equally satisfactory.

McKay²⁵ considers saline washings through the bronchoscope unsatisfactory. He and his associates have collected secretions on a cotton plug in the aspirator and have made their smears from this.

Every paper points out that Dudgeon and Wrigley,²⁶ in 1935, reported malignant cells in the sputum of 68 per cent of patients in a series of 38 cases with proved carcinoma of the lung. This work is quite obviously independent of that of Papanicolaou. It is most interesting to retrace the steps that led them to this study, for one finds it to be an adaptation of a technic reported by Dudgeon and Patrick²⁷ in 1927, in which scrapings of suspicious tissue from a variety of sources were spread on a slide and rapidly fixed, stained and examined. It appears that a pathologist, in his attempts at tumor diagnosis with smaller and smaller biopsies, has reached common ground with the cytologist.

UPPER GASTROINTESTINAL TRACT

The preparation of cellular spreads of gastric fluid must take into account certain factors not met in the secretion of the female genital and pulmonary tracts. Gastric fluid is less viscid, and the cells are much less numerous. Digestive ferments are present that will rapidly destroy the cells one wishes to study. Moreover, aspiration of stomach contents without roentgenologic check on the position of the tube runs the risk of failing to obtain a representative sample of the cells in the distal third of the stomach — an area where gastric carcinoma is most likely to occur.

Papanicolaou and Cooper²⁸ stress the importance of rapid fixation. They mix gastric fluid with an equal volume of 95 per cent alcohol, centrifuge for twenty minutes, spread the sediment on slides prepared with Mayer's albumen and then fix and stain them in their usual fashion. In a series of 27 cases of gastric cancer, positive smears were reported in 10 and suspicious ones in 7 others. There were no false-positive reports, but 9 of the 110 benign fluids were considered suspicious. Pollard and his associates,²⁹ using the same technic, found malignant cells in 35 to 40 per cent of patients with cancer of the stomach. They point out that satisfactory cytologic preparations are impossible in the presence of obstruction and gastric retention. This has also been emphasized by Ulfelder, Graham, and Meigs³⁰ who reported a high degree of accuracy (correct smears in 12 out of 14 patients with cancer of the stomach) when modifications in the method of collection were introduced. These include the use of a tube with additional openings in it and the introduction of physiological saline solution into the stomach in an effort to obtain a representative sample from the

entire organ. They stress the necessity of personal attention to the details of collection and preparation. Occasional false-positive smears were found by both Pollard and Ulfelder.

The malignant cells in gastric smears may be detected by application of the same criteria of abnormality postulated in the examination of other fluids. Most of the normal cells, however, are not gastric in origin, and familiarity with this normal picture is essential for accuracy.

URINARY TRACT

In dealing with urine one finds again that centrifugation is necessary to concentrate the cells in a small amount of sediment. Here also the use of albumen on the glass slides helps to retain the secretion during fixation and staining. Papanicolaou and Marshall³¹ add 95 per cent alcohol to freshly collected urine to retard cellular disintegration, although Chute and Williams³² discard this step in favor of immediate centrifugation and alcohol fixation of the sediment only.

Interpretation of urine smears is somewhat complicated by the lack of differentiation normally seen in transitional epithelium. Benign multinucleated cells are common. Moreover, many stages of activity are represented in any series of new growths of the urinary bladder, and a spectrum of grading is possible which crosses almost imperceptibly the line between benignancy and malignancy. Papanicolaou³³ reports 240 cases of which 76 are considered to have had carcinoma of the urinary tract. Fifty-eight (76 per cent) were diagnosed correctly by the smear. Three positive reports were rendered in the 164 patients considered not to have cancer, although 2 of them did have benign papillomas.

A much lower accuracy is reported by Chute and Williams. Only 55 per cent of cancers were detected, and there were 12 per cent false-positive reports. Most of the tumors missed were of low malignancy. Recently, Foot and Papanicolaou³⁴ reported a case of histologically proved noninvasive cancer of the renal pelvis invisible grossly but detected preoperatively by the cytologic method.

Both reports quoted in the paragraph above point out that carcinoma of the prostate may shed cells into the urine. Prostatic secretion collected by massage and immediately smeared, fixed and stained has been studied by Herbut and Lubin³⁵ and also by Albers and his co-workers³⁶. Both report an accuracy of over 85 per cent in cases of cancer if secretion is ample for smearing. A few positive smears that could not be confirmed histologically were also encountered.

SEROUS CAVITIES

Prior to the development of Papanicolaou's technique, more serious endeavor was applied to this type of fluid than to any other. A number of excellent reports³⁷⁻³⁸ are available, particularly since 1928.

The majority of pathologists centrifuge the fluid and fix and section the residue. The criteria used in diagnosis are dependable only when clusters of tumor cells in some recognizable architecture are present, although individual morphologic details have been carefully assessed and useful observations made on the nucleolar-nuclear ratio in benign and malignant cells.

A recent paper,³⁹ in which smears of sediment were used, reports an accuracy of only 56 per cent in cases in which cancer could be assumed to have involved the serous surfaces. This figure is no improvement over the 65 to 70 per cent accuracy reported in the past. There was, however, only 1 false-positive smear in this series whereas this type of error was common (25 to 50 per cent) in previous reports. One important deviation from Papanicolaou's technique should be noted in the procedure used by Phillips and McDonald³⁹: the smears were allowed to dry before fixation. In a series of 91 cases in which Papanicolaou's method was used without modification, the Vincent Memorial Laboratory⁴⁰ found malignant cells in 35 out of 45 cases. Four other positive smears were not corroborated histologically.

OTHER FLUIDS

The investigative curiosity of cytologists has extended to every conceivable material. It is known that rectal swabbings, duodenal aspirates, spinal fluid, ocular humors and many others are being examined. No formal reports have appeared, but it is probable that the fundamental technical principles are similar to those already described, with modifications to suit the character of each type of specimen.

DISCUSSION

It is obvious that exfoliative cytology can lead to the discovery of cancer in a variety of body areas, even when the lesion is invisible in size or histologically noninvasive. The results are most accurate when slides are prepared by a person interested in the procedure and willing to give time and attention to details that may facilitate interpretation, and when the slides are examined by someone thoroughly familiar with the cellular pattern of that particular fluid, prepared in that particular way.

Even under the best conditions available today there are two types of error—the false-negative and the false-positive cytologic report. The danger of the former is the unwarranted sense of security it gives to both patient and physician, it has analogies in any diagnostic procedure used in the cancer-detection clinic. This danger is so real that one must emphasize constantly the fact that failure to find cancer does not guarantee its nonexistence. It may be worth while in this connection to abandon any terminology of reporting that uses the words “negative,” “normal,” et cetera and to substitute phrases such as “no malignant cells found.”

The danger of the false-positive report is that radical therapy may be instituted with no attempt to find confirmatory evidence. Such patients should be subjected to frequent re-examination and managed according to a well planned study designed to determine exactly whence the abnormal cells arose. Serial section of any removed tissue is an essential feature of this program. As Gates and Warren point out, knowledge of the natural history of most malignant lesions is woefully meager in the early stages of disease. Now there is available a method that will permit more study of this type of case than has ever before been possible.

Looking at exfoliative cytology from quite another point of view, one may consider the chief disadvantage of the method to lie in its failure to *localize* the disease. For example, in a patient with malignant cells in the sputum and a small area of consolidation in one lung field, it is only the laws of probability that permit consideration of that area as the source of the cells. This will be true regardless of the eventual accuracy of the method and makes it essential that one discriminate very carefully in choosing between surgical procedures for confirmation and localization and surgical procedures for cure.

It may be best to think of the method as one that permits selection of some patients who are almost certain to have malignant lesions, for a repeatedly positive report from dependable sources is seldom wrong and warrants every possible effort at confirmation. By the same token, on the rare occasions when the malignant potential of a known tumor is in question, a positive smear should point the way to adequate cancer therapy.

CASE 35321

PRESENTATION OF CASE

First admission A twenty-nine-year-old married woman entered the hospital because of a nontender lump in her left breast.

She noticed this lump about six weeks before entry and it apparently had not increased in size since then. There had not been any bleeding from the nipple or soreness under the arm. The patient was nine and a half months post partum, having delivered a normal girl, her first child. She did not nurse the child because she did not believe she was emotionally suited to nursing. There was no weight loss or anorexia.

Except for the local lesion in the left breast, physical examination was entirely negative. The left breast was filled with a firm, grape-like cluster of nodules, densest in the inner middle quadrant. It was nontender, not fixed to the skin or chest wall and did not produce blood at the nipple on pressure. There was a bean-sized nodule in the left axilla.

A radial incision was made medial to the areola, and the involved area of breast tissue was excised. Immediate pathological examination showed no evidence of cancer, and the specimen received in the laboratory measured 5 by 4.2 cm and was diagnosed as sclerosing adenosis and periductal mastitis.

Second admission (ten months later) Soon after operation a small swelling developed near the operative incision, but this was considered to be an operative sequela. The patient received several doses of testosterone and then stilbestrol, with some improvement. However, because of the persistence of the mass and her continued anxiety, an aspiration was performed with return of old blood clot. It was believed that the lesion was a hematoma, and she was therefore admitted to the hospital for evacuation of it.

A circumareolar incision was made in the upper inner corner of the left breast. A considerable amount of blood clot was evacuated, together with a good deal of bright blood, and the incision was extended down along the line of the previous incision. The tissue was so necrotic and the bleeding so brisk that eventually a mastectomy was performed.

Third admission (four months later) After discharge the patient felt well and gained 6 pounds. About eight weeks before admission, however, she began to feel a slight pain in the upper outer quadrant of the right breast. She was examined by her physician seven weeks before entry, but no mass was palpable, however, the pain continued. One week before admission the patient was re-examined, and a mass was found in the right breast. She was therefore referred back to the hospital.

Physical examination showed an area of thickening, 2 by 3 cm, which was slightly firm, nontender and not well defined, in the upper, outer quadrant of the right breast. The scar of the left mastectomy was well healed.

On the second hospital day exploration of the right breast was performed.

DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W. TAYLOR This is to my knowledge the briefest physical examination of a patient that I have ever seen in a clinicopathological conference. So this case will simply form some sort of text on which we can hang a number of not too brilliant diagnoses.

Here is a patient with something the matter with her breast, which was explored, who got into trouble postoperatively and in whom a mastectomy finally had to be done. I think that is deplorable. The findings on exploration—sclerosing adenosis and periductal mastitis—represent some of the disintegrated segments of the old category of chronic cystic mastitis. Foote and Stewart¹ subdivided that clinical group of diseases, and I noticed with a good deal of amusement that often one of the residents in pathology is apt to make seven or eight diagnoses in that category on a single patient. The problem of the relation of this disease to malignant neoplasm is one that is very poorly clarified. Dr. Shields Warren,² some years ago, undertook to find out what relation this general group of diseases called chronic cystic mastitis bears to the subsequent development of cancer. In reviewing patients who had had partial breast excisions or partial amputations that he had followed up he found that the incidence of cancer was definitely increased. The series was large enough to be statistically valid. Unfortunately, from my viewpoint, he did not subdivide the disease into the various subdivisions that Foote and Stewart recommend. Therefore, it is impossible to say which one of these various categories is the most likely

to be associated with subsequent development of the malignant process. He did divide the cases into age groups and found that if cystic disease had been manifested in the twenties, the likelihood of subsequent cancer was vastly greater than if the first evidence of disease did not appear until the forties or fifties. In the latter age group the incidence of subsequent cancer was almost identical with that of a control population.

We have a young woman who had such a diagnosis made in relation to her breast. It was removed, and she reappeared rather promptly with an area in the other breast. This had first put in its appearance as a painful area. Nothing is said in the record about whether the pain was related to the menstrual cycle in any way. I am inclined to believe that probably it was, because most cases of breast pain that do not have a mass associated with them are apt to manifest themselves in the week or ten days prior to the menstrual period, and then diminish considerably with the onset of the period. She was examined, and nothing was found in the breast. Presumably, a thorough search was made because she had symptoms directing attention to that area. It does not say whether the examining physician elicited any tenderness in that part of the breast, but it seems very likely since that was the area in which she complained of pain. However, the record says that during examination no mass was observed.

Now we come to the brief physical examination that described the mass, but descriptions of masses made by someone else are rarely satisfactory. I suppose nowhere is it more necessary to have one's own hand conduct an examination and then interpret the findings than in the examination of an ambiguous lump. It was well enough defined so that a guess about the measurements could be hazarded. She had an area of induration presumably in the same area where she had discomfort. The location in the outer upper quadrant is significant, since that is where patients more often have painful nodularity or the manifestation of sclerosing adenosis or cystic mastitis. That is the usual site, because that quadrant is the one that contains the largest amount of breast tissue. Nothing is said about the axilla, and we might assume that the axilla showed no metastases. That is as far as I can go on that. The rest is pure conjecture. All I can say is that we have, I think, very wisely adopted the attitude that every lump in the breast may be a cancer and that the only safe assumption is that it is a cancer until the pathologist says it is not. The general policy we have in relation to breast tumors in this hospital, and again I say it is a wise one, is that all such lumps are to be subject to exploration without undue delay. It used to be said that there is no good Indian but a dead Indian. We could modify this and say the only place for a lump in the breast is in a bottle

in the pathology laboratory. As long as a woman is harboring or may be harboring a cancer, immediate operation is warranted. Also, of the major cancers that affect mankind, cancer of the breast, if caught at an early stage, offers one of the most favorable prognoses of any type of malignant neoplasm. Therefore, if I were seeing this patient, I would say, "I cannot tell you what it is. It does not matter what I think it is. The important thing is that it is possible it may be cancer. Therefore, you should submit to exploration without delay and I will put it up to a pathologist. If it is not cancer, if it is benign, you will have the peace of mind that comes from the knowledge that it is benign. You will not be subjected to undue mutilation. [It would be harder to convince this patient on that point, because of the experience of the previous simple exploration with its unfortunate results.] You will be able to resume your usual activities in at least a week, if not sooner, and you will go on your way rejoicing that you do not have cancer."

If I were further pressed by this particular patient, or a member of the family, I would say "No, I do not think we are dealing with cancer in this case." Why? Because none of the positive evidence of cancer or the presumptive physical evidence was present. Here is a mass that had developed rapidly from being not observed at all to being 2 or 3 cm in size. It was first manifested by pain. There was no adherence and no distortion—only an area of induration described as an area of thickening. Again, one would want to feel it with one's own fingers to interpret it, but to me it is just a thickness that is not characteristic of cancer. In view of the fact that she had previously had sclerosing adenosis and mastitis in the opposite breast, I should think that this was a further manifestation of the same disease, which is of obscure etiology. Whether Dr. Nathanson will relate it to hormonal disturbances, whether it was of vascular origin or on what basis it originated, I am unable to say. But, I think it is going to be again the same thing that was found in the opposite breast.

DR. TRACY B. MALLORY: Dr. Bartlett, will you describe your findings?

DR. MARSHALL K. BARTLETT: Naturally, it was very distressing to have this patient come back after operation with a residual mass in her breast. Because we had a pathological report of a benign lesion, it seemed safe to experiment a little with hormonal therapy, but it failed to produce any significant change in the lesion. During this period the patient and her family were not happy about the situation and presently sought the opinion of another surgeon. He observed it for a time and then finding a bluish discoloration of the skin, he aspirated it, and got some blood out of it that led him to the conclusion that probably it was an old

hematoma, and as related in the record, she was admitted for evacuation of the hematoma. At that time, the bleeding encountered was so massive that operation was limited to biopsy of the tissue. As a result of the report of that biopsy, the patient was seen by several consultants and, on their advice, I finally did a radical mastectomy on her. Her convalescence was uneventful, and she was well for several months, as you have been told. She finally came back complaining of the other breast in which I could find no lesion, but for obvious reasons I suggested re-examination in a few weeks. At that time there was a mass. This mass was then excised, and immediate pathological examination made. There was no evidence of carcinoma. However, when the final sections came through an opinion was expressed that led to a radical mastectomy on the opposite side.

CLINICAL DIAGNOSIS

Chronic cystic mastitis

DR TAYLOR'S DIAGNOSES

Sclerosing adenosis of breast
Periductal mastitis

ANATOMICAL DIAGNOSIS

Hemangiosarcoma of breast

PATHOLOGICAL DISCUSSION

DR MALLORY: This case represents complete failure on the part of the Department of Pathology, and of me personally, to detect a malignant lesion of the breast. When Dr Bartlett explored the first lesion in the left breast, I was present at the operation, and the tissue seemed so obviously benign that I did not consider it necessary to do a frozen section. We then put through a paraffin section and did find, as reported, adenosis.

At the time of the recurrence and the second biopsy, it became obvious that there was a malignant tumor, of endothelial origin, present in the breast.

DR JOSEPH C AUB: Which breast?

DR MALLORY: The left breast. It was a hemangioma growing with rapidity, so that we had to classify it as a hemangiosarcoma. At that time the radical mastectomy was done. The subsequent recurrence in the second breast was identical. Again, the biopsy looked perfectly benign grossly but on microscopical examination had the same type of malignant vascular tumor in it. When the recurrence appeared in the first breast, we went back to the original biopsy and found in one corner of one of our slides a little area, which had we paid attention to it, we should have recognized certainly as a hemangioma, if not as a malignant one.

DR RICHARD H WALLACE: Was the axilla involved on either side?

DR MALLORY: No, there was considerable question on both occasions whether or not radical mastectomy should be done. Very often these hemangiomas do invade the pectoral muscles. It was believed that if one was going to remove the pectoral muscles it did not add much to the operation to dissect the axilla.

Have you any comment, Dr Taylor?

DR TAYLOR: No, except that I am pleased to take a nose dive in such good company.

A PHYSICIAN: How long has it been since operation?

DR BARTLETT: About a year. The patient is all right at the present time.

DR TAYLOR: Was the second tumor an independent primary tumor or a metastasis?

DR MALLORY: I believe it was independent. It was in the other breast, and on the far side. If the recurrence had been close to the line of the original incision, one would think otherwise.

DR IRA T NATHANSON: I saw this patient with Dr Bartlett. The lesion in the right breast was a ring for sclerosing or blunt duct adenosis. We could not make a diagnosis of hemangiosarcoma although we entertained it in view of the findings in the left breast. Consequently, we decided to explore the area in order to establish the diagnosis.

The various types of sarcomas of the breast rarely metastasize to lymph nodes but usually spread through the blood stream, commonly to the lungs. Hence, simple mastectomy has been ordinarily considered adequate to control the local disease. However, sarcomas of the breast, particularly of hemangiomatous origin, may invade the pectoral muscles. This was seen on the left side, where radical mastectomy was performed for this type of invasion. Similarly, it was our opinion that radical mastectomy on the right side was also the procedure of choice in this patient, who was in excellent physical condition. It was considered that the slight additional risk was minor in comparison with the possibility of leaving residual disease in the muscle if simple mastectomy was elected.

CASE 35322

PRESENTATION OF CASE

A twenty-four-year-old married woman entered the hospital because of morning hemoptysis.

The patient had been well until shortly after a pregnancy and delivery under ether anesthesia eight months before admission, when she developed a chronic cough, particularly in the morning, productive of a tablespoonful of whitish-yellow, non-

foul sputum. This persisted and in the three months before entry became associated with a dull, aching and occasionally sharp twinge of right subscapular pain on coughing. The patient denied chills, fever, night sweats and other constitutional symptoms, but noted progressive fatigability and a 15-pound weight loss despite a good appetite. The fingernails seemed to change during this period from normal configuration to a clubbed appearance. Three weeks before entry the patient had the onset of morning hemoptysis from a teaspoonful of bright-red blood to bloody streaking of the sputum. This was a daily occurrence but was unassociated with new symptoms or change in other symptoms. Five years before admission the patient developed a firm, nontender, and otherwise asymptomatic mass in the right anterior cervical region, which was removed in another hospital and allegedly found to contain a "pocket of pus." About two years before admission she noted the gradual recurrence of a mass in the same region, with some increase in size up to the present.

The family and past histories were not remarkable. The patient denied known contact with tuberculosis.

Physical examination revealed a slender, well developed woman in no discomfort. There were several firm, nontender, freely movable, nodular masses in the right anterior cervical triangle—one measuring 2 by 3 cm, with adjacent 0.5-cm nodules on the sternomastoid muscle, and one measuring 2 by 5 cm in the supraclavicular fossa, which seemed to descend into the upper mediastinum. No other significant lymphadenopathy or abnormal masses were noted except for a slightly tender, freely movable mass, 2 by 5 cm, in the right breast and a similar mass, 2 by 3 cm, in the left breast. Early clubbing was noted in all fingernails. Examination of the chest revealed signs consistent with consolidation in the right upper lobe, most marked anteriorly. There were a Grade I short, blowing, basal systolic murmur and a split second sound at the base. The remainder of the physical examination was not remarkable.

The temperature was 98.6°F, the pulse 100, and the respirations 20. The blood pressure was 125 systolic, 70 diastolic.

Examination of the blood disclosed a white-cell count of 14,000, with 92 per cent neutrophils. The hemoglobin was 11 gm per 100 cc. Urinalysis revealed a + test for albumin and was otherwise negative. Sputum examination for acid-fast bacilli was negative. A skin tuberculin test was negative in dilutions of 1:100,000 and 1:10,000.

X-ray study of the chest revealed increased density in the anterior segment of the right upper lobe, with some degree of collapse and honeycombing in the lower portion of the lobe, interpreted as dilated bronchi. There was increased prominence of the right hilus, and some calcification was demonstrated in the right lung. The left lung was normal.

The findings were interpreted as "drowned" lung, secondary to obstruction in the right-main-stem bronchus.

On the fourth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR JOHN G. SCANNELL. In second-year medical school we were asked in an examination to enumerate and discuss the causes of hemoptysis and were expected to rattle off with a fair degree of assurance the fourteen (or was it seventeen?) diseases concerned. I wish I could muster the same assurance today. However, assuming that the hemoptysis was bona fide, and in the present case there is every reason to believe that it was, we must look to the bronchial tree for either a primary lesion or changes secondary to pulmonary hypertension. With no evidence for the latter, I think we can safely dismiss it and confine our attention to diseases that give rise to localized changes in the lungs, to a definite lymphadenopathy and to generalized systemic changes—namely, weight loss, chronic fatigue and clubbing. As a point of departure, may we see the x-ray films?

DR JAMES C. MCCORT. The examination of the chest reveals an increase in density of the anterior and apical segments of the right upper lobe. These segments are reduced in size. Within the involved segments there are radiolucent areas giving the segments a honeycombed appearance. This may be due to dilated bronchi and bronchioles. None of these radiolucent areas show a fluid level. There is a slight amount of fluid in the overlying pleura and in the minor fissure on the right side. The right-upper-lobe bronchus can be traced for a distance of 1 cm distal to its orifice, at which point it is narrowed and apparently blocked. There is no definite evidence of displacement of the trachea or mediastinum. Enlargement of the right peribronchial lymph nodes is present. There are also a few flecks of calcification in the peribronchial area, which may be within lymph nodes. The remaining lung fields are clear. The diaphragm is in its normal position. There is no blunting of either costophrenic sinus. The heart and vessels appear normal.

DR SCANNELL. Are you impressed by the curving deviation of the trachea to the left? I assume that is compatible with the large lymph node in the right cervical triangle described in the physical examination.

DR MCCORT. The cervical portion of the trachea does show a slight displacement to the left side, which may be due to the mass described in the right side of the neck. The exact amount of displacement is difficult to determine because there is slight scoliosis of the spine.

DR SCANNELL. We have, therefore, evidence of a lesion that involved bronchi of the order of

segmental bronchi, and hence presumably could be visualized and, perhaps, biopsied through a bronchoscope. There were also cervical lymph nodes that, according to the description given, were sufficiently abnormal to warrant biopsy. We are, however, called upon to make a diagnosis in advance of these diagnostic maneuvers.

In a patient of another sex and another age group, the diagnosis would be carcinoma until proved otherwise. The marked male-sex preference of bronchiogenic carcinoma is well known (usually estimated to be about ten to one), and in a patient in the twenties the unlikelihood of carcinoma is greatly increased. Except for these facts, however, the history of an unfamiliar cough, dull, aching chest pain, weight loss, chronic fatigue and, especially, early pulmonary osteoarthropathy are all highly suggestive, and the finding of a segmental lesion by x-ray examination and enlarged cervical, paratracheal and mediastinal lymph nodes is almost confirmatory. To rule out cancer requires a positive diagnosis of something else, presumably benign tumor, a chronic suppurative process or tuberculosis.

We might mention other rare tumors, notably chorionepithelioma and lymphoma. The former is, perhaps, suggested by the onset following pregnancy, but that is all that we have in its favor and I shall discard it. Lymphoma of the lung is rare, particularly with endobronchial involvement, but it is known to occur, it may invade the bronchial tree, and certainly is suggested here in view of the rather striking cervical-lymph-node involvement and the evidence of considerable hilar lymphadenopathy by x-ray examination. In addition, we have the evidence of a chronic disease without great blood loss. I am a little disturbed by the apparent lack of fever.

In the case of lymphoma of the lung reported from this hospital by Dr Churchill¹ in 1947, there were several points of similarity to the present case. The patient was a woman, she complained of a dull aching pain beneath the right scapula, and her physical signs were those of consolidation—that is, an open lobar bronchus with solidified lung adjacent to it. On the other hand, she had no lymph-node involvement, no clubbing, no hemoptysis and no anemia. She had had symptoms some six months or so, with episodes of fever. However, the case presented apparently a solitary lymphoma of the lung itself, and not, as we must postulate in the case under discussion, a lymphoma situated in the right bronchial node and invading and involving the right-upper-lobe bronchi secondarily. Certainly, the cervical lymph nodes suggest lymphoma in that they were freely movable, firm, nontender and of considerable size. Were they of tuberculous origin I would expect them to be less discrete, more uniformly involved and possibly displaying some calcification on x-ray study. Furthermore, a def-

inite diagnosis of tuberculosis was ruled out by negative sputums and negative tuberculin tests. An acid-fast node eroding into a bronchus is, in a way, an attractive diagnosis to make for this patient, but I do not see how we can support it.

Of the possibilities outlined above, benign tumor was mentioned. The patient was a woman, she was young, she had had some bleeding, and she had segmental secondary changes. However, this diagnosis fails to account for the enlarged lymph nodes, except the very rare bronchial adenoma with extensive satellite-lymph-node involvement. In any case, were the latter involved secondary to a pulmonary lesion, I would expect greater involvement of the subcarinal node, and as we can see by the overexposed film of the chest, the carina is quite sharp and normal in appearance. Incidentally, were the lesion a highly undifferentiated bronchiogenic carcinoma of the oat-cell variety, I should expect the same distortion of the carina as is present in this case.

Turning to a more hopeful diagnosis, in view of the onset of cough following an inhalation anesthesia, chronic lung abscess must be carefully considered. Chronic, somewhat productive cough, hemoptysis and clubbing are in its favor. Absence of fever, the presence of cervical lymph nodes and the location in the anterior and apical segments of the upper lobe as opposed to the posterior segment of that same lobe are against it. Both by history and on x-ray study there was no evidence of a sequestration of lung tissue. Furthermore, no penicillin or streptomycin had been given, which might obscure the natural history of the disease.

Bronchiectasis limited to the right upper lobe is a possibility, but here again the history is relatively short and atypical, the x-ray picture, in spite of the suggestion of dilated bronchi, is not that of saccular, dry bronchiectasis in this area, and the cervical lymph nodes are not accounted for. Bronchiectasis secondary to a foreign body is always a possibility, especially in view of the previous anesthesia, but we have no evidence on which to base this diagnosis.

A closely related lesion—namely, chronic non-specific pneumonitis of the cholesterol type²—certainly merits our consideration. The history is not at all out of line, although one would expect more evidence of an active inflammatory process at some time in its development and less striking hemoptysis, and although marked regional lymphatic involvement is the rule (and is evident here on the chest film), again the presence of these definitely abnormal cervical lymph nodes is difficult to explain. Strangely enough, at no time was viral pneumonia diagnosed and antibiotics given.

One always wonders, particularly in this hospital, about the diagnosis of sarcoid in puzzling lymphatic and pulmonary lesions, but if I understand Dr Freiman³ aright, even considerable enlargement

foul sputum This persisted and in the three months before entry became associated with a dull, aching and occasionally sharp twinge of right subscapular pain on coughing The patient denied chills, fever, night sweats and other constitutional symptoms, but noted progressive fatigability and a 15-pound weight loss despite a good appetite The fingernails seemed to change during this period from normal configuration to a clubbed appearance Three weeks before entry the patient had the onset of morning hemoptysis from a teaspoonful of bright-red blood to bloody streaking of the sputum This was a daily occurrence but was unassociated with new symptoms or change in other symptoms Five years before admission the patient developed a firm, nontender, and otherwise asymptomatic mass in the right anterior cervical region, which was removed in another hospital and allegedly found to contain a "pocket of pus" About two years before admission she noted the gradual recurrence of a mass in the same region, with some increase in size up to the present

Bronchiectasis secondary to a foreign body is always a possibility, especially in view of the previous anesthesia, but we have no evidence on which to base this diagnosis.

A closely related lesion—namely, chronic non-specific pneumonitis of the cholesterol type²—certainly merits our consideration. The history is not at all out of line, although one would expect more evidence of an active inflammatory process at some time in its development and less striking hemoptysis, and although marked regional lymphatic involvement is the rule (and is evident here on the chest film), again the presence of these definitely abnormal cervical lymph nodes is difficult to explain. Strangely enough, at no time was viral pneumonia diagnosed and antibiotics given.

One always wonders, particularly in this hospital, about the diagnosis of sarcoid in puzzling lymphatic and pulmonary lesions, but if I understand Dr Freiman³ aright, even considerable enlargement

of the hilar lymph nodes is rarely associated with pressure or obstructive phenomena, a point of differentiation from lymphoma or carcinoma

Metastatic carcinoma is also a definite possibility, and in this case would incriminate the thyroid gland or some silent primary focus. We have little evidence to single out the former, and no real evidence to indicate the latter — for example, a silent hypernephroma. At some risk, I am going to disregard the bilateral breast masses

Clearly, a most helpful next step in the diagnosis would be either a bronchoscopic biopsy or a cervical-lymph-node biopsy, and one of these, I suspect, was the operation performed on the fourth hospital day. When I embarked upon this discussion, I was inclined toward a nonspecific chronic pneumonitis with marked hilar involvement, believing that the history, the age and sex of the patient, the x-ray picture and the physical signs were consistent with this diagnosis, but as I reconsider it, I am more than ever impressed by the cervical lymphadenopathy and therefore elect lymphoma with bronchial encroachment and erosion as the probable diagnosis

CLINICAL DIAGNOSIS

Malignant lymphoma

DR SCANNELL'S DIAGNOSIS

Malignant lymphoma

ANATOMICAL DIAGNOSIS

Malignant lymphoma, Hodgkin's type

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN On the ward, the differential diagnosis rested mainly between tuberculosis and lymphoma. Dr Joseph C. Aub, who was on service at that time, believed that "the most

reasonable single diagnosis is lymphoma occluding the bronchus"

One of the cervical lymph nodes was removed, and it showed the characteristic microscopical findings of Hodgkin's disease. Dr Benedict reported that bronchoscopy of the right bronchial tree was difficult because of the apparent pressure on it from the right side, but with the right-angle telescope, the orifice of the upper lobe was readily visible and found to be markedly stenotic. No outcropping could be seen.

The patient was then given x-ray treatment over a period of eight days, 300 r per day, the anterior and posterior right upper mediastinum each receiving 900 r and the supraclavicular region 600 r.

The patient did not return to this hospital, but it was later learned that there was a good response to this treatment for about a year. She then entered another hospital very sick with fever, weight loss, anemia, pleural effusion and ascites. After tapping of the chest, a mass was observed within the right lung and after tapping of the abdomen, the liver and spleen were found to be enlarged. X-ray treatment was again given, but this time there was no improvement. However, a course of nitrogen mustard produced a miraculous change in the patient. The mass in the lung practically disappeared, and the patient was able to be herself again. This remission lasted for about three weeks, but she then returned with pain in the opposite chest. Nitrogen mustard again brought relief. She has just recently been discharged from the hospital after her third remission, which is about two years since admission to this hospital.

EDUCATION OF THE FAMILY PHYSICIAN

OF ALL the manifold problems besetting the medical profession today in its desire to provide the public with the best medical care, that of restoring the family physician to a position commensurate with his contribution to society, by improving standards of general practice, appears to be one of the most pressing

The pattern of practice is obviously changing, and the next few years will undoubtedly bring profound alterations in the organization for the provision and distribution of medical care, as well as in the methods of paying for it. Nevertheless, there can be no change in what is fundamental to the best medical practice—namely, a solid foundation of well trained family physicians. True, the public has strayed away from reliance on the family doctor owing largely to overemphasis of

specialization, so highly developed and widely touted in all phases of American life, but there seems now to be a trend back to him, with a beginning awareness of the proper relation between the general physician, as the first echelon, and the specialist, whom he will call when needed. Not the least of the influences in this change may be certain types of group practice in which several general practitioners or family physicians work on an equal footing with various specialists to whom they refer patients as indicated. Regardless of whether group medicine is to become the accepted pattern and whether prepayment insurance becomes the solution for the economic difficulties, nothing will succeed in replacing the family physician as the most important cog in the whole system.

Actually, the profession itself is largely responsible for the devaluation of the family doctor. Clinical teaching in the medical schools is largely provided by specialists, and postgraduate education of interns and residents in teaching hospitals is chiefly carried out by specialists and research workers. The house staff tends to believe that going into practice is a less worthy career than one devoted to teaching and research—a step downward, rather than merely a parallel road. The family physician who refers problem cases to these hospitals is often looked down upon by the house staff, and referred to patronizingly as the "L M D." Perhaps teaching hospitals should arrange for qualified general practitioners to enter into certain phases of teaching. The family doctor is likewise to blame by trying to do too much and becoming so busy he cannot keep up with attendance at meetings or with the medical literature. Instead he would do well to put such educational activities on a required list each week. Too often he has had insufficient hospital training, and the opportunities for good training for this type of work are too few and poorly organized.

The economics of medicine adds to the process of his devaluation. Although he must combine the skills of diagnostician, therapist for at least 75 per cent of the problems confronting him, adviser for family and individual social problems, and public-health adviser, for all these diffuse but vital functions he is undercompensated in comparison with many specialists.

Finally, there appears little doubt that the process of board certification has gone too far, par-

ticularly in internal medicine. Certainly, a great many certified "internists" are, actually, family physicians. Yet the prize of a certificate by the Board of Internal Medicine is such that men planning to devote themselves to medicine rather than to surgery or other specialties requiring technical skills are often motivated in planning their hospital training by getting so many years of credit—putting in time, so to speak—rather than by an intrinsic desire for postgraduate study per se. Too little consideration is given to the fact that medical education is a lifelong process, and even though a man goes into practice he must continue to develop himself educationally in the wards and at conferences of the hospital of his community. Although two years of internship training should be a minimum for the family physician it might be very desirable to revive the old apprentice system whereby the young physician works for a year under the supervision of an older staff member of a community hospital. If this could be effectively carried out, it would probably be more valuable than an additional hospital residency.

Recently the Council on Medical Education and Hospitals of the American Medical Association has included a residency in general practice in its "Essentials of Approved Residencies and Fellowships." This residency is designed to attract men who wish to become family physicians, and is not conceived with the thought that specialty boards will accept it as meeting in part their training requirements. This and other movements are in line with the trend toward elevating standards of general practice as required by modern life, and in elevating the position of the modern family physician. In Boston the Faulkner Hospital has announced a new internship of two years, designed to provide optimum training in this field. Emphasis is placed on internal medicine, to which twelve months are devoted, with another year divided among pediatrics, obstetrics and surgery. A period devoted to medicine and pediatrics is to be spent at a larger teaching hospital in affiliation. The internship is announced as being especially designed for men who wish to become family physicians.

Such programs should go far toward improving the level of general practice and should result in attracting more and better men into this field. Perhaps one of the most important factors in combating the demand for compulsory health insurance

will be the development of many well trained family physicians, with a better sense of proportion, both within the profession and on the part of the public, concerning specialization.

"WHAT IS A MAN PROFITED?"

HOFFMAN, elsewhere in this issue of the *Journal*, considers the clinical results of leukotomy in 42 patients treated by psychosurgery at the Veterans Administration Hospital in Bedford, Massachusetts. The study covers the years 1947 and 1948. All but one of the patients were schizophrenics whose illness and hospitalization had been of two to twenty years' duration. Results at the time of the study showed 4 patients to be dead, 14 out of the hospital, either discharged or on trial visits, 16 still in the hospital but so improved that they could have been living at home, and 8 still in the hospital and requiring hospital care because of continued disturbed behavior.

These results are comparable to those more recently released by the Yale University News Bureau on the Connecticut Co-operative Lobotomy Study, a joint project of the Department of Psychiatry and Mental Hygiene of the Yale University School of Medicine and the three state mental hospitals of Connecticut. This study, organized in 1946, reports on 294 postoperative patients, mostly severe cases of schizophrenia, who had been hospitalized for an average of five years prior to operation.

According to this report 36 per cent of the patients were able to return to their homes within a year after operation, and a total of 61 per cent had shown definite improvement in their mental health. An important measure of their status is their capacity for work. Of the 294 patients less than 75 per cent were capable of work before their operation. After the lobotomy more than 25 per cent were working full time, and an additional 38 per cent were employed on a part-time basis.

So far as objective behavior is concerned, impulsive, overactive and aggressive traits, suicidal attempts and constant refusal of food had disappeared in over three fourths of the group. Subjectively, more than 85 per cent of the patients had lost such disturbing symptoms as depression, obsessive-compulsive behavior and anxiety.

These figures are certainly encouragingly in favor of the operation, but Hoffman presents also the

other side of the argument, considering his cases from the point of view of qualitative results. The behavior and frequently the comfort of the patients is admittedly improved, but it is by the process of subtraction, he implies, and never by addition.

The tendency, he points out, is to overlook "the very real and permanent losses to the integrity of the personality" sustained as a result of operation. In the removal of the disease focus an uncertain quantity of vital tissue indispensable in making up the total personality of the patient is also removed. Even in consideration of a certain general vagueness concerning just what constitutes a soul, some observers have described post-lobotomy patients as persons who had lost this ill defined but apparently indispensable part of their individuality. Perhaps it would be more acceptable to say that many of them had lost the vital spark of their personality, or the particular spiritual value compounded of the emotions and the reason, and consisting of the ability to know sorrow and happiness, peace and anxiety, compassion and understanding that puts the final touches on the human being.

Psychosurgery is one of the fruitful experiments that medical science has occasionally to offer, but its subjects must still be selected with the utmost care. Perhaps, as Greenblatt and Myerson* suggest, the refinements of topectomy will avoid some of the disadvantages of lobotomy.

*Greenblatt M and Myers P G. Psychosurgery. *New Eng J Med* 240 1006-1017 1949

SOLOMON'S KITCHEN

KING SOLOMON, it is said, on a visit to Hebron, found the people of the district so poor and yet so loyal that he established a fund to provide them with daily food "until the end of the world." Presumably Solomon's fund has been exhausted, but so strong is tradition that the custom has been maintained even to the present time.

Last December, however, the continuity of the practice established by the wise king was at last about to be broken. The cupboard was bare. Then on Christmas eve trucks of the United Nations International Children's Emergency Fund rolled into the area.

A million refugees, *UNICEF News* reports, are waiting out their destiny in the desert about Israel. Food and shelter are their first problem, idleness

comes next. Schools have been started for the children, but there are no fields for the men to till, no wool for the women to weave. UNICEF is now able to bring some measure of relief to the half million children and pregnant and nursing women among these refugees—a relief, purchased out of the allocation of \$6,411,000 made to the area by the executive board, that comes from all over the world.

The United States, Canada and Denmark have sent milk, cod-liver oil has come from Iceland, and margarine from Australia and Belgium. Meat, wheat and flour have come also from Australia, and wheat and flour from Ethiopia, dried fruit has been sent from South Africa and Yugoslavia, rice from the Dominican Republic, Italy and Siam, and soap from New Zealand.

Palcstine is but one of the areas where the world's present misery makes such aid as that furnished by UNICEF imperative. In the first year of the program's operation 84,000,000 supplementary meals were provided in Austria. Shoes and blankets are now being distributed in Bulgaria. Czechoslovakia, a donor as well as a recipient country, has received over \$3,000,000 in supplies, with the government contributing \$1,000,000 and the people having raised an additional \$300,000.

In Greece 670,000 children and women, of whom 250,000 are refugees, receive supplementary meals, over a million Italian children are fed daily. Meals are provided in Yugoslavia, a BCG antituberculosis vaccination program is under way in Morocco, health workers are being trained in China. Danish teams of BCG vaccinators are at work in India, and a UNICEF Medical Mission is operating in Pakistan. Children are being fed in the Philippines.

The small countries, it is interesting to note, are leading in the response to the United Nations appeal for children, and of these Iceland, with a per capita contribution of \$4, leads all the rest. Other material donations have come from Australia, New Zealand, South Africa, Canada, Mozambique. Czechoslovakia raised a total of \$1,500,000, \$300,000 of which was for UNICEF. Yugoslavia and Austria have made their contribution, and even Italy has raised a quarter of a million dollars.

If the strength of a nation, as has been written, lies in the hearts of its people, then the world may yet struggle through its present misery to a better way of life.

ticularly in internal medicine. Certainly, a great many certified "internists" are, actually, family physicians. Yet the prize of a certificate by the Board of Internal Medicine is such that men planning to devote themselves to medicine rather than to surgery or other specialties requiring technical skills are often motivated in planning their hospital training by getting so many years of credit—putting in time, so to speak—rather than by an intrinsic desire for postgraduate study per se. MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

PHYSICIANS' HANDBOOK ON BIRTH AND DEATH REGISTRATION

The Massachusetts Department of Public Health has arranged with Edward J Cronin, secretary of the Commonwealth, to send copies of the tenth edition of the *Physicians' Handbook on Birth and Death Registration* to all practicing physicians and boards of health in Massachusetts. This handbook is valuable to physicians because it gives the important facts that physicians should know regarding registration requirements and procedures.

Additional copies can be obtained by application to the Secretary of State's office, State House, Boston 33, Massachusetts.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Research Publications Association for Research in Nervous and Mental Disease. Volume XXVII. *The Frontal Lobes. Proceedings of the Association, December 12 and 13, 1947*. New York 8°, cloth, 901 pp, with 237 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$12.50.

Fifteen years ago the Association published its volume on the localization of function in the cerebral cortex. The present volume deals with the frontal lobes and the material is divided into four parts: biology, experimental studies, clinical studies and frontal lobotomy. There are twenty-seven articles in this volume of the Research Publications, twenty-one of which are now out of print and unobtainable from the publishers or the Association. The series is very valuable and should be in all medical libraries. The present volume should be available to all neurologists and psychiatrists.

Industrial Hygiene and Toxicology. Volume I. Frank A Patty, editor. 8°, cloth, 531 pp, with illustrations and tables. New York: Interscience Publishers, Incorporated, 1948. \$10.00.

This volume is the first of a set of two projected volumes. Eleven specialists have contributed to this part, which is devoted to the various aspects of industrial hygiene. Some of the topics include personal and environmental factors in fatigue and competence, physiologic effects of abnormal atmospheric pressure, the mode of entry and action of toxic materials, sampling and analysis of atmospheric contaminants, radiant energy and radium (including poisoning by radium and thorium), ventilation, occupational dermatoses, the visible marks of occupation and occupational diseases, fire and explosion hazards of combustible gases, vapors and dusts, respirators and respiratory protective devices and dust and its role in occupational diseases. The literature noted is printed as footnotes on the pertinent pages. There is an extensive index of subjects. The type, printing and paper are excellent. Although this volume is large, it weighs only 3 pounds. Volume II, to be published later, will be devoted to various toxic compounds. The set is recommended for all medical public-health and industrial-plant libraries.

NOTICES

ANNOUNCEMENT

Dr Elmore M Campbell announces the opening of an office for the practice of medicine at 187 East Cottage Street, Dorchester.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The National Gastroenterological Association will hold its fourteenth scientific session at the Hotel Somerset in Boston, on October 24-26, 1949.

Among the outstanding speakers to present papers at the convention will be Dr Owen H Wangersteen, professor of surgery, University of Minnesota Medical School, Dr Frank H Lahey, Dr William B Castle, and Dr Maxwell Finland, of Boston, Dr George Crile, Jr, Cleveland, Ohio, Dr J M T Finney, Jr, Baltimore, Maryland, and Lord Alfred Webb-Johnson, president of the Royal College of Surgeons, London, England, who will be a guest of honor at the banquet to be held on Tuesday evening, October 25.

At the annual banquet to be held at the Somerset, the winner of the National Gastroenterological Association's 1949 prize award contest for the best unpublished contribution on gastroenterology or an allied subject, will receive the prize of \$100 and a certificate of merit.

Immediately following the convention on October 27-29, 1949, the Association is sponsoring a course in gastrointestinal surgery at the Boston City Hospital.

Further information concerning the program and details of the course may be obtained by writing to the secretary, National Gastroenterological Association, 1819 Broadway, New York 23, N Y.

AMERICAN PUBLIC HEALTH ASSOCIATION

The annual meeting of the American Public Health Association and related organizations will be held in New York City from October 24 to 28, with joint headquarters at the Hotel Statler and Hotel New Yorker. At the two general sessions of the Association the Lasker Awards for 1949 and the Sedgwick Memorial Medal will be presented, and the address of the president, Dr Charles F Wilinskas, of Boston, will be read.

Details regarding the program may be obtained from Dr Reginald M Atwater, Executive Secretary, American Public Health Association, 1790 Broadway, New York City.

AMERICAN ACADEMY OF PEDIATRICS

The American Academy of Pediatrics will hold its annual meeting in San Francisco, California, at the Palace Hotel, November 14 to 17, 1949.

PAN-AMERICAN CONGRESS OF PEDIATRICS

The second Pan-American Congress of Pediatrics (Tenth District of American Academy of Pediatrics) will be held in Mexico City, at the Del Prado Hotel, from November 2 to 5. The third National Congress of Pediatrics of the Mexican Society of Pediatrics will be held in Mexico City from October 30 to November 10.

INTERNATIONAL COLLEGE OF SURGEONS

The annual assembly and convocation of the International College of Surgeons, United States Chapter, will be held in Convention Hall, Atlantic City, from November 7 to 12.

The program will include scientific sessions on general surgery, eye, ear, nose and throat surgery, gynecology and obstetrics, urology, and orthopedic, thoracic, plastic and neurologic surgery. Special surgical clinics will be held in Philadelphia hospitals on November 7.

All doctors of medicine interested in surgery are invited. Further information regarding the program may be obtained from Dr Arnold S Jackson, secretary of the Chapter, at the Jackson Clinic Madison 4, Wisconsin. Hotel reservations may be made with E D Parrish, Haddon Hall, Atlantic City, New Jersey.

Such shocking exhibitions of dyed heads as are occasionally met with in the streets, in this change loving age, when fashionable people think they can color their skins and their hair with as much ease as politicians turn their coats under a new administration, show the necessity of a more perfect and expeditious mode of accomplishing the metamorphosis

Boston M & S J, August 8, 1849

NOTES FROM THE MEDICAL EXAMINER

IDENTIFICATION OF BLOODSTAINS — II

The proof that a stain has been caused by blood is a significant step in its identification¹ To show that it has been caused by human blood is of much greater importance

Before the beginning of this century the characterization of the species origin of bloodstains was made solely on the basis of the morphology of the red cells Although there are well recognized species differences in the size and shape of the intact mammalian erythrocyte, the effects of autolysis, hemolysis, drying and other mechanical distortion are such as to relegate this method of species identification to one of minor importance today

In 1901 Uhlenhuth² introduced the immunologic tests for human blood He showed that it was possible to prepare a specific antihuman rabbit serum by repeatedly injecting a rabbit with human blood The rabbit serum, when layered with a dilute solution of human blood, caused a precipitate to form at the interface The principle of this test forms the basis of present medicolegal tests for species identification of blood

Uhlenhuth's initial experiment was simple and qualitative It failed to reveal the fact that in many cases antisera against the blood of a particular animal also show cross reactions with the blood of other animals Thus, antihuman serum will probably react with the blood of monkeys and apes, and will occasionally react with the bloods of many other animals, even those remotely related These cross reactions are dependent upon a number of factors, some of which are not understood At present there is no certain method of preparing a high-titer specific antiserum by the use of a single animal Some animals fail to produce strong antisera, others produce antisera that are non-specific

The specificity of an antiserum may be improved by absorption of the undesired antibodies³ If an antihuman serum is found to exhibit an undesired cross reaction with dog blood, it may be mixed with dilute dog blood, allowed to stand several hours and then centrifuged The resulting serum will no longer react with dog blood, but will retain

its antihuman properties By such absorption it is likely that much of the "general animal" antibodies will be removed also, and that undesired cross reactions with any other animal bloods will be reduced greatly In other words, nonspecific antibodies tend to be nonspecifically absorbed

Because human blood is a complex mixture of proteins, antihuman-blood rabbit serum contains a mixture of antibodies Some of these are capable of reacting with most of the soluble proteins of human origin, regardless of whether they are blood or not Wiener⁴ has suggested the use of antihuman hemoglobin serums instead These may be prepared by injection of rabbits with washed, laked human erythrocytes It is then possible to identify human blood in one simple test, without the necessity of preliminary chemical tests to establish the presence of hemoglobin Hemoglobin is a poor antigen, with it the production of strong antisera is difficult However, the inconvenience in preparation of antihuman hemoglobin serum is outweighed by the advantages gained in its use

Antihuman hemoglobin serums frequently show a cross reaction with human serum The undesired antiserum factor may be removed conveniently by "in vivo" absorption within the rabbit Hektoen and Welker⁵ have shown that if multiple antigens are injected into an animal multiple antibodies are formed, and that each may be removed individually during the "negative phase" by an injection of its corresponding antigen Accordingly, the antiserum factor of an antihemoglobin rabbit may be removed "in vivo" by injection of the animal with an appropriate amount of hemoglobin-free human serum If the animal is bled during the "negative phase" of twelve to forty-eight hours thereafter, the rabbit serum will react with human hemoglobin, but not human serum

It is frequently useful for medicolegal purposes to prepare a general-animal-blood antiserum This is done by subjecting several rabbits to a series of injections of a mixture of bloods from many animals, exclusive of human beings When the antibody titer has reached a satisfactory level, a single injection of human blood is administered, and the animals are bled during the "negative phase" The best antisera are pooled An unknown bloodstain is then tested against human hemoglobin rabbit serum and antianimal rabbit serum If it reacts with the former and not the latter, the stain is of human blood, and if with the latter and not the former, it is of animal origin

nants, radiant energy and radium (including poisoning by
radium and thorium), ventilation, occupational dermatoses,
the visible marks of occupation and occupational diseases,
fire and explosion hazards of combustible gases, vapors and
dusts, respirators and respiratory protective devices and
dust and its role in occupational diseases. The literature
noted is printed as footnotes on the pertinent pages. There
is an extensive index of subjects. The type, printing and
paper are excellent. Although this volume is large, it weighs
only 3 pounds. Volume II, to be published later, will be de-
voted to various toxic compounds. The set is recommended
for all medical, public-health and industrial-plant libraries.

Dorchester

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The National Gastroenterological Association will hold its
fourteenth scientific session at the Hotel Somerset in Boston,
on October 24-26, 1949.

Among the outstanding speakers to present papers at the
convention will be Dr Owen H Wangensteen, professor of
surgery, University of Minnesota Medical School, Dr Frank
H Lahey, Dr William B Castle, and Dr Maxwell Finland,
of Boston, Dr George Crile, Jr, Cleveland, Ohio, Dr J M T
Finney, Jr, Baltimore, Maryland, and Lord Alfred Webb-
Johnson, president of the Royal College of Surgeons, London,
England, who will be a guest of honor at the banquet to be
held on Tuesday evening, October 25.

At the annual banquet to be held at the Somerset, the
winner of the National Gastroenterological Association's
1949 prize award contest for the best unpublished contribu-
tion on gastroenterology or an allied subject, will receive
the prize of \$100 and a certificate of merit.

Immediately following the convention on October 27-29,
1949, the Association is sponsoring a course in gastrointestinal
surgery at the Boston City Hospital.

Further information concerning the program and details
of the course may be obtained by writing to the secretary,
National Gastroenterological Association, 1819 Broadway,
New York 23, N Y.

AMERICAN PUBLIC HEALTH ASSOCIATION

The annual meeting of the American Public Health Asso-
ciation and related organizations will be held in New York
City from October 24 to 28, with joint headquarters at the
Hotel Statler and Hotel New Yorker. At the two general
sessions of the Association the Lasker Awards for 1949 and
the Sedgwick Memorial Medal will be presented, and the
address of the president, Dr Charles F Wilinskas, of Boston,
will be read.

Details regarding the program may be obtained from Dr
Reginald M Atwater, Executive Secretary, American Public
Health Association, 1790 Broadway, New York City.

AMERICAN ACADEMY OF PEDIATRICS

The American Academy of Pediatrics will hold its annual
meeting in San Francisco, California, at the Palace Hotel,
November 14 to 17, 1949.

PAN-AMERICAN CONGRESS OF PEDIATRICS

The second Pan-American Congress of Pediatrics (Tenth
District of American Academy of Pediatrics) will be held in
Mexico City, at the Del Prado Hotel, from November 2 to 5.
The third National Congress of Pediatrics of the Mexican
Society of Pediatrics will be held in Mexico City from October
30 to November 10.

INTERNATIONAL COLLEGE OF SURGEONS

The annual assembly and convocation of the International
College of Surgeons, United States Chapter, will be held in
Convention Hall, Atlantic City, from November 7 to 12.

The program will include scientific sessions on general
surgery, eye, ear, nose and throat surgery, gynecology and
obstetrics, urology, and orthopedic, thoracic, plastic and
neurologic surgery. Special surgical clinics will be held in
Philadelphia hospitals on November 7.

All doctors of medicine interested in surgery are invited.
Further information regarding the program may be obtained
from Dr Arnold S Jackson, secretary of the Chapter, at the
Jackson Clinic, Madison 4, Wisconsin. Hotel reservations
may be made with E D Parrish, Haddon Hall, Atlantic City,
New Jersey.

Such shocking exhibitions of dyed heads as are occasionally met with in the streets, in this change loving age, when fashionable people think they can color their skins and their hair with as much ease as politicians turn their coats under a new administration, show the necessity of a more perfect and expeditious mode of accomplishing the metamorphosis

Boston M & S J, August 8, 1840

NOTES FROM THE MEDICAL EXAMINER

IDENTIFICATION OF BLOODSTAINS — II

The proof that a stain has been caused by blood is a significant step in its identification.¹ To show that it has been caused by human blood is of much greater importance.

Before the beginning of this century the characterization of the species origin of bloodstains was made solely on the basis of the morphology of the red cells. Although there are well recognized species differences in the size and shape of the intact mammalian erythrocyte, the effects of autolysis, hemolysis, drying and other mechanical distortion are such as to relegate this method of species identification to one of minor importance today.

In 1901 Uhlenhuth² introduced the immunologic tests for human blood. He showed that it was possible to prepare a specific antihuman rabbit serum by repeatedly injecting a rabbit with human blood. The rabbit serum, when layered with a dilute solution of human blood, caused a precipitate to form at the interface. The principle of this test forms the basis of present medicolegal tests for species identification of blood.

Uhlenhuth's initial experiment was simple and qualitative. It failed to reveal the fact that in many cases antisera against the blood of a particular animal also show cross reactions with the blood of other animals. Thus, antihuman serum will probably react with the blood of monkeys and apes, and will occasionally react with the bloods of many other animals, even those remotely related. These cross reactions are dependent upon a number of factors, some of which are not understood. At present there is no certain method of preparing a high-titer specific antiserum by the use of a single animal. Some animals fail to produce strong antisera, others produce antisera that are non-specific.

The specificity of an antiserum may be improved by absorption of the undesired antibodies.³ If an antihuman serum is found to exhibit an undesired cross reaction with dog blood, it may be mixed with dilute dog blood, allowed to stand several hours and then centrifuged. The resulting serum will no longer react with dog blood, but will retain

its antihuman properties. By such absorption it is likely that much of the "general animal" antibodies will be removed also, and that undesired cross reactions with any other animal bloods will be reduced greatly. In other words, nonspecific antibodies tend to be nonspecifically absorbed.

Because human blood is a complex mixture of proteins, antihuman-blood rabbit serum contains a mixture of antibodies. Some of these are capable of reacting with most of the soluble proteins of human origin, regardless of whether they are blood or not. Wiener⁴ has suggested the use of antihuman hemoglobin serums instead. These may be prepared by injection of rabbits with washed, laked human erythrocytes. It is then possible to identify human blood in one simple test, without the necessity of preliminary chemical tests to establish the presence of hemoglobin. Hemoglobin is a poor antigen, with it the production of strong antisera is difficult. However, the inconvenience in preparation of antihuman hemoglobin serum is outweighed by the advantages gained in its use.

Antihuman hemoglobin serums frequently show a cross reaction with human serum. The undesired antiserum factor may be removed conveniently by "in vivo" absorption within the rabbit. Hektoen and Welker⁵ have shown that if multiple antigens are injected into an animal multiple antibodies are formed, and that each may be removed individually during the "negative phase" by an injection of its corresponding antigen. Accordingly, the antiserum factor of an antihemoglobin rabbit may be removed "in vivo" by injection of the animal with an appropriate amount of hemoglobin free human serum. If the animal is bled during the "negative phase" of twelve to forty-eight hours thereafter, the rabbit serum will react with human hemoglobin, but not human serum.

It is frequently useful for medicolegal purposes to prepare a general-animal-blood antiserum. This is done by subjecting several rabbits to a series of injections of a mixture of bloods from many animals, exclusive of human beings. When the antibody titer has reached a satisfactory level, a single injection of human blood is administered, and the animals are bled during the "negative phase." The best antisera are pooled. An unknown bloodstain is then tested against human hemoglobin rabbit serum and antianimal rabbit serum. If it reacts with the former and not the latter, the stain is of human blood, and if with the latter and not the former, it is of animal origin.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

PHYSICIANS' HANDBOOK ON BIRTH AND DEATH REGISTRATION

The Massachusetts Department of Public Health has arranged with Edward J Cronin, secretary of the Commonwealth, to send copies of the tenth edition of the *Physicians' Handbook on Birth and Death Registration* to all practicing physicians and boards of health in Massachusetts. This handbook is valuable to physicians because it gives the important facts that physicians should know regarding registration requirements and procedures.

Additional copies can be obtained by application to the Secretary of State's office, State House, Boston 33, Massachusetts.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Research Publications Association for Research in Nervous and Mental Disease. Volume XXVII. *The Frontal Lobes. Proceedings of the Association, December 12 and 13, 1947*, New York 8^o, cloth, 901 pp, with 237 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$12.50.

Fifteen years ago the Association published its volume on the localization of function in the cerebral cortex. The present volume deals with the frontal lobes and the material is divided into four parts: biology, experimental studies, clinical studies and frontal lobotomy. There are twenty-seven articles in this volume of the Research Publications, twenty-one of which are now out of print and unobtainable from the publishers or the Association. The series is very valuable and should be in all medical libraries. The present volume should be available to all neurologists and psychiatrists.

Industrial Hygiene and Toxicology, Volume I. Frank A. Patty, editor. 8^o, cloth, 531 pp, with illustrations and tables. New York: Interscience Publishers, Incorporated, 1948. \$10.00.

This volume is the first of a set of two projected volumes. Eleven specialists have contributed to this part, which is devoted to the various aspects of industrial hygiene. Some of the topics include personal and environmental factors in fatigue and competence, physiologic effects of abnormal atmospheric pressure, the mode of entry and action of toxic materials, sampling and analysis of atmospheric contaminants, radiant energy and radium (including poisoning by radium and thorium), ventilation, occupational dermatoses, the visible marks of occupation and occupational diseases, fire and explosion hazards of combustible gases, vapors and dusts, respirators and respiratory protective devices and dust and its role in occupational diseases. The literature noted is printed as footnotes on the pertinent pages. There is an extensive index of subjects. The type, printing and paper are excellent. Although this volume is large, it weighs only 3 pounds. Volume II, to be published later, will be devoted to various toxic compounds. The set is recommended for all medical, public-health and industrial-plant libraries.

AMERICAN ACADEMY OF GENERAL PRACTICE

The American Academy of General Practice will hold its second Scientific Assembly in St. Louis, Missouri, on February 20-23, 1950. Further information may be obtained by writing Mr. Mac F. Cahal, Executive Secretary, 406 West Thirty-Fourth Street, Kansas City 2, Missouri.

GRANTS AND FELLOWSHIPS IN
CANCER RESEARCH

The Committee on Growth of the National Research Council, acting for the American Cancer Society, is accepting applications for grants and fellowships. Applications for new grants in cancer research will be received until October 1. Investigators now receiving grants will be notified individually regarding application for the extension of these grants. Final decision on applications will be made in most cases soon after February 1, 1950. Grants approved at this time ordinarily will become effective July 1, 1950.

Fellowship applications may be submitted at any time. Those received prior to November 1 will be acted upon by the Committee on Growth in December. Those received between November 1 and March 1 will be acted upon in April. Fellowships ordinarily will begin July 1, though this date may be varied at the request of the applicant.

During the past year the American Cancer Society, Inc., on recommendation of the Committee on Growth, has approved research grants and fellowships totaling over \$2,000,000.

Communications regarding grants and fellowships should be addressed to Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue, N. W., Washington 25, D. C.

SHORT-TERM DUTY AVAILABLE FOR
ARMY MEDICAL RESERVISTS

The Department of the Army has recently published Special Regulation 140-210-10, which authorizes commanders of Army installations to place volunteer reserve officers of the Medical, Dental, and Veterinary Corps on active duty for periods of from 1 to 29 days a month, but not more than 90 days of active duty in a fiscal year. Officers selected will be placed on active duty in the grade in which currently commissioned in the Officers' Reserve Corps.

Active duty will be performed at an Army installation or activity situated within the vicinity of the officer's home. No officer will be ordered to active duty where travel to duty station is involved. However, authorization whereby officers may volunteer as ship's surgeon on an Army transport for a round-trip voyage is given in the regulations.

ASSOCIATION OF SCHOOL PHYSICIANS

The interim committee appointed at the Amherst meeting convened at Hotel Sheraton, Worcester, on July 24. School physicians should watch these columns and those of the *Newsletter* of the Massachusetts Department of Public Health for notices and announcements.

ALVARENGA PRIZE

On July 14, 1949, the College of Physicians of Philadelphia awarded the Alvarenga Prize for 1949 to Owen Harding Wangensteen, M.D., Ph.D., professor of surgery, University of Minnesota, for his contributions to the etiology and therapy of gastric and duodenal ulcer. Dr. Wangensteen will deliver the Alvarenga Lecture on this subject at the College of Physicians of Philadelphia on November 2.

The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia to be awarded annually by the College of Physicians on the anniversary of the death of the testator, July 14, 1883.

ROSEOLA INFANTUM (EXANTHEM SUBITUM)*

WILLIAM BERENBERG M.D.,† STANLEY WRIGHT M.D.,‡ AND CHARLES A. JANEWAY M.D.§

BOSTON

THE problem of fever in infancy is one of the most common and difficult ones confronting the general practitioner and pediatrician. In 1910 Zahorsky¹ described a febrile exanthem occurring in infants and young children which he termed roseola infantum. This disease was characterized by a relatively asymptomatic febrile course of three to five days, followed by the appearance of a morbilliform eruption. Several years later Veeder² helped confirm this syndrome as a specific pathologic entity and suggested the name exanthem subitum. Since that time the disease has attracted wide interest in pediatric circles. However, since patients afflicted with this condition are rarely seriously ill or hospitalized, the average medical student does not see many cases and consequently roseola has become to many physicians an unfamiliar, little appreciated disease that is frequently misdiagnosed or unrecognized. The name roseola itself has been something of a handicap since it is so easily confused with the terms rubeola (measles) and rubella (German measles). This is all the more surprising since there is increasing evidence that roseola is probably the most common febrile exanthem in children and infants under three years of age.³

During the ten-year period 1937-1947 181 cases were seen at the Children's and Infants' hospitals, Boston. This group is hardly representative of the type of disease ordinarily encountered in practice since the average patient is not ill enough to be referred to a hospital for care. It is in great measure made up of children who have had convulsions, who have been more prostrated than usual, or in whom the duration of the febrile stage has been unusually protracted. In order to make the following descriptive discussion more typical of what may be expected, we have also drawn on their own experience

in practice as well as on the various descriptions in the literature.

FREQUENCY

Many authors⁴⁻⁷ have commented on the surprising frequency with which they encountered roseola in their own practice once they were on the lookout for the condition. Breese³ followed 70 newborn babies for a year with special attention to the number who developed roseola, and observed 11 cases, an incidence of 16 per cent. In view of the age-distribution curve he concludes that approximately 30 per cent of all children develop the disease eventually. In our own experience it has been the most common exanthem encountered under two years of age. As pointed out below, there is reason to suspect that the disease may be almost universal in one form or another under the age of five years.

SEASONAL INCIDENCE

Roseola may occur in any month of the year although it appears to be most prevalent in late spring and mid-autumn.^{2, 5} In patients admitted to the Children's Hospital the peak months were May and October.

SEX AND AGE INCIDENCE

No difference in incidence between the sexes was observed. As is implied in its name, roseola infantum is principally a disease of infants and young children. In our own series the youngest patient seen was four months of age, and the oldest eight years. All those who have described this disease are in complete agreement about the general age-distribution curve (Fig. 1) fully 95 per cent of cases occurring between the ages of six months and three years. Zahorsky¹ refers to a case seen when the patient was two weeks old, and Cutts¹⁰ describes a typical example in a woman of thirty-one years.

PREFEBRILE PRODROMES

These are almost invariably absent, although occasionally the child may have short periods of unimpressive, ill defined irritability and malaise.

*From the Department of Pediatrics, Harvard Medical School, and the Children's and Infants' hospitals, the Children's Medical Center.
†Instructor in Pediatrics, Harvard Medical School; associate physician, Children's and Infants' hospitals.
‡Member, Department of Pediatrics, University of Rochester; Rochester, New York; formerly assistant resident physician, Children's and Infants' hospitals.
§Thomas Morgan Roach, Professor of Pediatrics, Harvard Medical School; physician-in-chief, Children's and Infants' hospitals.

ONSET

The onset is usually abrupt from the point of view of fever. The child may be slightly irritable

FIGURE 1 Age Distribution in Roseola (181 Cases, 1937-1947)

or listless, but the mother's attention is ordinarily first attracted to him because he feels warm. On taking the temperature she is usually surprised to

FIGURE 2 Clinical Course in Roseola, with Drop in Temperature by Crisis

find it elevated to 103 to 105°F. The patient, despite the high fever, is most commonly active and alert, and appears quite well.

CLINICAL COURSE

The course of the disease is chiefly characterized by a constant or intermittent, high fever for three to five days. Less often the fever persists for as long as seven to nine days. The temperature is often normal or slightly elevated in the morning, only to rise to 104 to 105°F by early evening. Generally, the patient appears relatively well, although with the increase in fever he may become restless, irritable, listless or wakeful. Older children may complain of headache and abdominal pain.

FIGURE 3 Clinical Course in Roseola, with Drop in Temperature by Lysis

In most cases the only symptoms are those which might be directly ascribed to fever itself irrespective of the cause. Appetite is ordinarily but slightly impaired, and vomiting may occur if large amounts of foods are ingested while the patient is febrile. A fair proportion of our patients had mild coryza or cough, but the interpretation of this was difficult since many cases occurred during the season when upper respiratory infections were prevalent in the community. The temperature usually drops to normal by crisis coincident with or immediately preceding the appearance of the rash. In a smaller number of cases, especially those with intermittent fever, a fall in temperature by lysis may occur over a period of twenty-four to thirty-six hours (Fig 2 and 3).

PHYSICAL FINDINGS

There is usually a paucity of physical findings, and those present are neither diagnostic nor constant

General Appearance

Almost all patients look and act quite well. They are usually alert, happy and playful. With unusually high fever they may appear listless or irritable, as previously described above. In a very small number of cases they are acutely ill and prostrated, and are occasionally seen in apparent collapse.

Pulse and Respirations

These are usually elevated in proportion to the fever and show no special features.

Pharyngitis

Fully a third of our patients had some mild diffuse catarrhal inflammatory reaction of the pharyngeal mucosa. This was never striking enough to make the examiner satisfied to ascribe the fever to bacterial pharyngitis.

Tonsillitis

A small number of patients with typical roseola have a well defined tonsillar inflammation with occasional exudative follicles. These have developed while the patients were on chemotherapy, and direct cultures even in untreated patients have yielded no significant pathogens. These observations suggest that tonsillar involvement may be due to the roseola virus although there is no reason to doubt that coexistent or secondary bacterial infection does occur.

Enanthem

There is no true or constant enanthem in this disease. However an increasing number of patients have been found¹¹ who exhibit what are apparently areas of lymphoid hyperplasia in the region of the uvula and soft palate. In our experience these appear to consist of pin-point elevations on the mucous membrane that are slightly pinker in color than the surrounding mucosa. They are only rarely striking and are easily missed unless the examiner looks specifically for them with adequate illumination. They may appear at any time during the first few days of the disease and usually persist for a few days beyond the appearance of the rash.

Otitis

About a quarter of our patients demonstrated a mild catarrhal otitis media, which was considered to be a reflection of the type of inflammatory pharyngeal reaction just described. This was not ordinarily associated with significant pain and subsided rapidly without specific therapy. Extensive catarrhal otitis or suppurative change developed in relatively few patients, and it was believed that

these represented secondary or coexistent bacterial invasion. Cultural studies failed to reveal the constant presence of any particular organism in the small group who required paracentesis or drained spontaneously.

Pulmonary Changes

Physical examination of the lungs has not revealed any significant abnormalities. In a small percentage of the more severely ill patients we have observed nonspecific increase in interstitial pulmonary markings by roentgenographic examination. The significance of this observation is open to question in view of the normal roentgenograms obtained in the majority of patients so examined.

Lymphadenopathy

The importance and incidence of significant lymph-node enlargement has long been debated. Various authors^{5, 11, 12} have maintained that suboccipital, posterior cervical and postauricular adenopathy is a frequent and important finding. Others^{2, 3, 13, 14} have been unable to confirm this observation. It has also been pointed out¹⁵ that although suboccipital adenopathy is frequent in roseola, the other causes of lymph-node enlargement in this region in childhood are so common that its true significance is open to question. Much of this confusion may be explained by the inadequacy of reviews of hospital records in this respect unless the various observers were especially interested in looking for such changes and specifically recorded their absence as well as presence. In 70 cases in our series in which the patients were examined carefully and repeatedly for adenopathy, some enlargement of suboccipital or posterior cervical lymph nodes was nearly always demonstrable. The degree of enlargement was variable but was considered to be obviously significant in the majority of cases. It was also noted that in many cases the lymph nodes first became palpable on the second or third day of disease and continued to increase in size over the next few days. They rarely reached a size of more than 0.5 to 1.5 cm. The nodes are usually moderately firm, nontender and freely movable. Enlargement may persist for several weeks.

Rash

It has been emphasized that roseola is the only exanthem typically characterized by a pre-eruptive period of high fever, after which the child becomes well when the rash erupts. The rash occurs predominantly on the neck and trunk only, although it may involve the proximal extremities, postaural regions and face. Its appearance ordinarily coincides with the subsidence of fever, or it may follow this by as much as thirty-six to forty-eight hours. As its name implies, the eruption is rose pink. It is characterized chiefly by discrete, small, often irregu-

lar-shaped macules, occasionally maculopapules, measuring 2 or 3 mm in diameter and fading on pressure. They have no tendency to grouping and are distinctly separated although on rare occasions with an extensive eruption they coalesce. The individual macules are often surrounded by a whitish areola. There is no pruritus or desquamation.⁶ The eruption usually lasts for twenty-four to forty-eight hours and then fades completely without residual pigmentation. We have seen a few typical cases in which the rash appeared and faded completely within two to four hours. This raises the obvious possibility of missing a rash that occurs in an area usually covered by clothing and may be relatively fleeting (Fig 4).

LABORATORY STUDIES

Blood

Although the white-cell count is classically described as being low in this condition, it is worth

FIGURE 4 Post-Febrile Skin Eruption in Roseola
Example of a rather florid eruption

emphasizing that if one sees the patient in the first twenty-four to thirty-six hours, some slight leukocytosis is the rule. During this period the white-cell count is usually in the range of 12,000 to 15,000, with a slight increase in neutrophils. Occasionally, counts are as high as 20,000 to 22,000 at this time. Ordinarily by the second day and invariably by the third day there is a definite leukopenia accompanied by an absolute neutropenia and a relative lymphocytosis. The white-cell count usually returns to normal within a week, but the lymphocytosis may persist for a longer period. No abnormal cells have been encountered on smear, and no changes in hemoglobin or red cells are demonstrable.

Nose and Throat Cultures

Almost all the patients in this series had such cultures with results similar to what one would expect to obtain from the nasopharyngeal flora of any comparable asymptomatic group of well children.

Cerebrospinal Fluid

Because of the high incidence of febrile convulsions in our series, many lumbar punctures were performed. All these spinal fluids were sterile and showed no alterations in sugar, globulin or quantitative protein. In only 1 case was any significant number of cells (25 lymphocytes per cubic millimeter) encountered.

Urine

Routine urine examinations, which were performed in most of the patients studied, showed no variations from the normal.

Virus Studies

Previous attempts³ to isolate a filterable agent have proved unsuccessful. In 6 of our patients studies¹⁶ were carried out on nasopharyngeal washings and cerebrospinal fluid collected during the febrile pre-eruptive stage, which were inoculated into mice intranasally, intracerebrally and intraperitoneally. Similar material was inoculated into chick embryos in 2 cases. To date, no specific viral agent has been isolated.

EPIDEMIOLOGY

The striking age incidence between six months and three years and the tendency for increased numbers of cases to appear in the spring and fall were noted above.

INCUBATION PERIOD

In 6 cases there was positive evidence of intimate exposure preceding the appearance of roseola, the incubation period was between ten and fifteen days as reported in two separate epidemics.^{7, 17} However, on 3 occasions the disease appeared thirty to ninety days after a known intimate exposure, without any history of subsequent contact. Garvin¹⁸ is stated to have observed cases of the disease forty-one days apart in twins, and Davies¹⁹ has seen cases one hundred and sixty days apart in siblings. The shorter incubation periods unquestionably are the more likely, especially since there is no proof that there was not an intermediate unknown exposure in cases occurring thirty to ninety days after contact. However, these long incubation periods are of considerable interest.

COMMUNICABILITY

Roseola is a disease of rather poorly defined communicability. There is rarely any spread to sib-

lings,²⁰ who are almost always outside the susceptible age group in the average family. All those engaged in pediatric practice are familiar with the minor waves of increased frequency of the disease on occasion. There almost never is any well defined epidemic spread, although 2 such cases are reported from foundling homes.^{7, 19} We have not seen the disease spread on the general wards of the Infants' Hospital, where these patients are cared for with the same gown precautions used on all infants.

IMMUNITY

In roseola as in all other exanthems, well established second cases of infection are reported,^{21, 22} although these are unusual. For all practical purposes one attack affords permanent immunity. Despite the claim of some early authors that roseola was an anomalous form of German measles¹² or measles, it has been well established that there is no cross immunity and that roseola stands as a specific entity.

ETIOLOGIC AGENT

Although no specific etiologic agent has ever been demonstrated, the incubation period, clinical course, blood changes, failure to respond to chemotherapy and immunologic concepts all lend credence to the idea that roseola is produced by a viral agent.

PROGNOSIS

As indicated above the prognosis in this disease is supposed to be excellent almost by definition. However, we have recently encountered several infants who became desperately ill at the height of the disease despite an early sense of well being. One ten-month-old infant, who fulfilled all the diagnostic criteria including subsequent typical rash, became critically ill on the second day of disease. He went into a shock-like state of collapse, with rapid, thready pulse, dyspnea, cyanosis and a cold, mottled skin. This did not appear to be due to hyperpyrexia. For a period of a few hours it appeared unlikely that he would survive, although he eventually responded to symptomatic shock therapy.

COMPLICATIONS

The commonest complication encountered in our series was convulsions. The actual incidence in hospital and consultation practice is quite high, and in some years convulsions occurred in as many as a third of the patients. This incidence is obviously false and artificial, for a convulsion was often the chief reason for hospitalizing the patient. It must be borne in mind that the vast majority of patients with roseola are never sufficiently ill to warrant hospital care or study. The incidence of convulsions has been variably reported as 0.7 per cent,¹⁸ 6 per cent²³ and 50 per cent,²⁴ depending on the source of material with the lowest incidence in cases reviewed in general practice and the highest

in hospital practice. The seizures are usually generalized, tonic or clonic in character, and of short duration, without sequelae. Presumably, they are febrile in origin. We have only observed alterations of cerebrospinal fluid in this group in 1 case. Lumbar puncture was performed on almost all the convulsive patients in our series. The occurrence of seizures was most common in patients in whom the onset was very abrupt, with sudden, unusually high fever.

Several patients appeared unusually drowsy after one or a series of convulsions. A relatively small number of patients were stuporous for one to twenty-four hours. An example of striking encephalitis in a twelve-year-old boy has been reported.²⁵

Two of our patients had postconvulsive hemiplegias, which cleared in two to five days respectively. A case in which such a hemiplegia persisted for ten weeks has been reported.²⁶ Such complications are almost certainly due to the preceding convulsions rather than to roseola per se.

DIFFERENTIAL DIAGNOSIS

The commonest error in diagnosis is to call the acute illness acute pharyngitis, otitis media or pneumonia and to ply the patient with unnecessary chemotherapeutic agents. The eruption is often misdiagnosed as a toxic rash, prickly heat or eczema. An important error in diagnosis is that of drug rash since it may affect the patient's care in a subsequent illness in which there is real need for chemotherapy. Often the attending physician prescribes one of the sulfonamides or penicillin in the absence of a specific diagnosis because of the unusually high fever. When the rash appears a diagnosis of drug rash is made, and the patient is erroneously labeled as sensitive to the chemotherapeutic agent. Drug rashes are more apt to be confluent and more widespread and less apt to be confined chiefly to the trunk as in roseola. If the medication is continued and the rash fades, the diagnosis of sensitivity may be eliminated.

The following exanthems are to be differentiated from roseola.

Chicken pox The vesicular character of this rash is unique enough so that erroneous diagnosis is unlikely.

Scarlet fever This usually has a shorter invasion period, more constant although less elevated temperature, more angina, tongue changes and febrile state of acute illness when the rash appears. The appearance of the rash is, of course, quite different, and neutrophilic leukocytosis is the rule.

Measles The presence of cough, coryza, Koplik spots, conjunctivitis and the intensification of fever and malaise with the appearance of the eruption should serve to differentiate this disease from roseola.

German measles The rash and lymphadenopathy here more closely resemble roseola than in any other condition. The rash of German measles is apt to be more widespread and may coalesce. Its frequent epidemic incidence is most helpful in diagnosis. The absence of a high temperature and the early appearance of the rash during the febrile stage should serve to differentiate this condition from roseola.

Infectious mononucleosis Approximately 5 to 10 per cent of patients with infectious mononucleosis develop a rubella-like rash or scarlatiniform eruption in the early febrile stage of the disease. The longer course, more striking and more generalized lymphadenopathy, splenomegaly and laboratory findings of many atypical lymphocytes on smear with the development of a positive heterophil-antibody agglutination should distinguish this condition.

TREATMENT

The treatment of roseola is purely symptomatic. The patient should be kept at rest and given fluids freely. Aspirin is helpful in keeping the patient more comfortable by virtue of its antipyretic effect. In patients with a sudden high temperature, phenobarbital may well be employed to raise the convulsive threshold and prevent seizures from occurring. The sulfonamides, penicillin and streptomycin are of no value.

DISCUSSION

Roseola infantum, a well defined, common exanthem of infancy and early childhood, has been recognized in approximately 15 to 30 per cent of children carefully followed by those familiar with the disease. The known factor of its incidence raises a number of interesting speculations concerning its epidemiology. The comparative infrequency of cases before the age of six months suggests transplacental passive immunization of the infant by its mother such as occurs in measles. On the other hand, the rarity of cases beyond the age of three years is unlike the situation in measles and is particularly remarkable in view of the demonstrated susceptibility of occasional older patients. It raises the possibility that almost all susceptible persons may be exposed and may contract the disease in the first three years of life. On the other hand, the infrequency of epidemics, suggesting that the degree of contagiousness is probably not high, is difficult to reconcile with such a concept.

This situation could be explained by widespread dissemination of the infective agent, perhaps by numerous adult carriers, universal susceptibility after disappearance of the antibodies received from the mother and the existence of atypical modified forms of the disease. In view of the manner of spread of the epidemics reported by Barenberg¹² and Cushing,⁷ it was concluded that the disease was

transmitted by adult carriers. If true, this would explain the sporadic occurrence of roseola and the usual absence of a known exposure.

The occurrence of asymptomatic, inapparent or very mild forms of infection has been recognized with other virus diseases such as poliomyelitis, infectious hepatitis and mumps. That this may occur in cases of roseola is quite possible. Moreover, it is logical to assume that, as in measles, there may be a period between four and eight months of age when immunity passively acquired from the mother gradually recedes. During this period the antibody titer may well be low enough to allow the infant to contract a modified form of the disease. All pediatricians have seen many infants and young children who acted as though they had roseola but in whom the rash was never demonstrated. Again, the rash may be so fleeting as to defy detection unless it is constantly watched for day and night. The idea that an atypical, mild, modified form of the disease exists is held by various authors.^{3, 11, 17} If adult carrier states are common, there may well be numerous cases of unrecognized modified infection occurring around the age of six months. Indeed, if these hypotheses are correct, it may not be too far fetched to assume an almost universal incidence of both recognizable and unrecognized modified disease in infancy and early childhood to explain the unusual occurrence of a common virus infection that is rarely seen before the age of six months or after the age of three years.

Although roseola is certainly a benign disease in the vast majority of cases, we have observed a small but definite number of patients with a more serious clinical picture. It hardly seems possible that a disease of infancy with such a marked febrile reaction should invariably be benign. As the disease is now defined and interpreted, it is dismissed from differential diagnostic consideration if the patient succumbs, and in such a case its recognition is impossible since its distinguishing feature, the rash, only appears at the time of clinical recovery. In view of some of our experiences, we have speculated that some cases of so-called "sudden death" in infancy may eventually be proved to be unusually severe, unrecognized forms of roseola. The chief pathological findings described by Farber²³ in many of his reported cases of sudden death were interstitial pneumonia and cerebral edema — lesions of a type that might be expected in a viral infection.

SUMMARY

1 Roseola infantum (exanthem subitum) is a relatively asymptomatic febrile disease, with a paucity of physical findings, of three to five days' duration followed by a morbilliform eruption.

2 It is the commonest exanthem of infancy. The hypothesis is offered that it may be an almost universal infection under the age of five years.

3 It is most prevalent in spring and autumn.

4 There is no difference in incidence between the sexes

5 Fully 95 per cent of cases occur between the ages of six months and three years

6 The clinical course, physical findings and hematologic changes are described

7 The incubation period is defined and the communicability and epidemiology discussed. The possibilities of a large carrier population and a modified form of the disease are raised

8 The evidence favors a viral etiologic agent

9 The prognosis is for the most part excellent. The possibility of the existence of more serious unrecognized and occasionally fatal variants of the usual clinical picture is raised

10 The recognized complications include convulsions, encephalitis and rarely hemiplegia

11 The disease can be differentiated from the other common exanthems

12 The treatment is purely symptomatic

THE MAJOR UROLOGIC CONSIDERATIONS IN PARAPLEGIA*

HERBERT S TALBOT, M D,† MELVIN K LYONS, M D,‡ AND ARTHUR J BASSELL, M D§

FRAMINGHAM, MASSACHUSETTS

THE health of the upper urinary tract in paraplegia is, except for one hazard, dependent upon the health and function of the bladder. That exception is a tendency toward the formation of renal stones during prolonged recumbency or inactivity. But this tendency is itself greatly exaggerated by infection and stasis, both of which are sequelae of vesical dysfunction. From the hour of injury, therefore, there can be no temporizing with the care of the bladder if the dangerous consequences of the neurogenic disorder are to be averted or diminished.

After any severe spinal-cord injury, there is often a period of spinal shock. This is marked by the suppression of all reflex activity below the level of the injury. The bladder, sharing in this common suppression, is unable to evacuate its contents and

requires artificial drainage. It has generally been considered that the bladder is atonic during this period. Nesbit and Lapides¹ have suggested that the atony is not primary, but occurs only if, as a result of inadequate drainage, the bladder wall has become overdistended and decompensated. It may be that in such cases tonus is maintained through the agency of the intrinsic ganglions of the vesical wall. Munro,²⁻⁴ on the other hand, states that cystograms taken on many patients shortly after injury regularly reveal complete atony. One thing is quite apparent,—that in many cases, if not always, a return of tonus becomes evident before the detrusor is yet capable of the strong, sustained contractions necessary to bring about voiding. This return may be delayed or totally impeded by overdistention, the avoidance of which, therefore, becomes a chief aim of early treatment. For it must be apparent that a decompensated bladder wall may in time undergo changes that will irreversibly alter its functional capacity.

A concept thus emerges that has not been emphasized in the literature on this subject—that the alterations in function following interference

with the nerve supply of the bladder must be interpreted in terms of an organ that has also been subjected to other drastic structural alterations. There may come a time when, even if the innervation might be miraculously restored, the functional result would still be poor. The avoidance and treatment of such alterations, whether they come early or late, then becomes a major factor in the urologic care of these patients.

During the war, there was some justification for the performance of early cystostomies in forward areas. In civilian conditions, there is none. Catheter drainage with tidal irrigation is easily the method of choice. Permanent suprapubic cystostomy has fewer and fewer advocates as time passes, and as attention focuses more sharply upon true rehabilitative treatment rather than mere expediency.

With the patient's emergence from the phase of spinal shock, the bladder almost invariably resumes its reflex activity. Exceptions occur when the spinal reflex centers have themselves been destroyed, leaving an autonomous bladder, or when the bladder wall has so changed as to be incapable of normal response to the stimuli directed to it. Such changes may be the result of prolonged or excessive distention, contraction such as frequently follows prolonged suprapubic drainage, or infection with consequent fibrosis. The reflexly acting bladder is that which is commonly called "automatic," an unfortunate term, since it does not accurately describe the functional status. Correctly designated, an autonomous bladder is one that has been completely divorced from the central nervous system by destruction of the spinal reflex center that mediates micturition, or by interruption of the fibers concerned in the reflex arc. It has a fairly characteristic pattern of behavior—hypertonicity with frequent ineffectual contractions. It is always leaking but never empty. The neural function is mediated through the ganglions within the vesical wall, aided by the intrinsic response of smooth muscle to the stimulus of stretch. This type of bladder is characteristically associated with destructive lesions of the sacral segments and the cauda equina.

The re-establishment of satisfactory function of the reflex bladder postulates urethral voiding, a bladder of sufficient capacity to act as a reservoir for convenient intervals and with reasonable consistency, a bladder that is capable of emptying itself completely or almost completely, and a sufficient degree of control to avoid involuntary escape of urine. Satisfactory urethral voiding involves the closure of all fistulas whether of deliberate or accidental origin. The latter are usually the result of infection, most often penurethral, they generally emerge at the penoscrotal junction and practically always require surgical repair. Occasionally they are seen in association with urethral diverticula. A previously established suprapubic

sinus that does not heal promptly during urethral catheter drainage should have a definitive surgical closure. Pate and Bunts⁵ have described two cases of fatal peritonitis in patients in whom the fistula had closed at the abdominal wall but had not become completely obliterated. Such occurrences illustrate the danger inherent in spontaneous closure of a long-standing fistula.

The bladder capacity need not be excessive, 8-10 ounces (240-300 cc.) is quite satisfactory, and 7 ounces (210 cc.) is probably safer. The greater inconvenience of slightly more frequent emptying is amply compensated for by avoidance of the hazards of overdistention. The only known stimulus to detrusor contraction, and thus to the emptying of the bladder, is stretch. This is a dynamic rather than a static phenomenon. It is dependent upon increasing intravesical pressure. Normally, the contractions thus elicited can be inhibited by impulses from higher centers. This inhibitory mechanism is the chief agent of voluntary control of micturition. Another is the voluntary contraction of the external sphincter, which is always accompanied by reflex inhibition of the detrusor. In the paraplegic patient, both these voluntary control mechanisms are commonly lost, and the bladder has returned to a state of uninhibited reflex function similar to that of infancy. The inhibitory impulses, however, are perhaps not the only manifestations of control from higher levels impinging upon the reflex center for micturition. The control of tonus, as well as certain co-ordinating and integrating factors are also, according to some observers, transmitted along descending fibers.⁶⁻⁹ Possibly as a result of their interruption, the reflex bladder may be hypertonic to a greater or lesser degree, and its detrusor, although it contracts powerfully, does so with diminished efficiency.¹⁰ In order to establish regularity and consistency of function, the familiar phenomenon of the conditioned reflex is invoked, through the use of tidal drainage and habit training, as first recommended by Munro,^{2, 4, 11, 12} and now widely adopted. The hygienic value of tidal drainage constitutes a further advantage in its use.

The occasional paradox of a hypertonic bladder that cannot empty itself completely is readily resolved. Lack of co-ordination and integration of detrusor activity has already been mentioned as a factor in dysfunction. This is most prominent in the autonomous bladder. The internal orifice, which is in fact the edge of the detrusor, shares in the hypertrophy due to frequent ineffectual contractions. This may be of sufficient degree to produce obstruction at the vesical neck. Superimposed infection or fibrosis, or both, may cause rigidity, contributing further to dysfunction. The opening of the internal orifice is a reciprocal concomitant of detrusor contraction resulting from the mechanical arrangement of the muscle fibers. It is probably

incorrect, certainly incomplete, to ascribe micturitional dysfunction to so-called neurogenic sphincteric disturbance. When persistent residual urine exists in association with bladder-neck obstruction, transurethral resection is indicated.^{13, 14} Even when such obstruction cannot be demonstrated cystoscopically, but when in spite of a good detrusor there is residual urine or retention of urine, resection is justified. Spasm of the external sphincter has been described¹⁵ and should be excluded before surgery is undertaken, but the importance of this phenomenon as an obstacle to voiding has not yet been conclusively demonstrated.

When a satisfactory and reasonably consistent capacity has been achieved and when the bladder empties itself completely, there remains the question of control. The problem is to train the patient to void at his own convenience, anticipating the involuntary reflex emptying of the bladder. Obviously, the patient must be able, first, to initiate micturition and, second, to know when to do so. Fortunately, a majority of paraplegic patients retain some degree of sensation associated with vesical filling. This may manifest itself in various ways. Some experience a suprapubic or generalized abdominal pain or a burning referred to the penile urethra. Others exhibit autonomic reactions such as sweating, chills or headache. A number, however, have no sensory recognition of a full bladder. Among this group, reliance must be placed on timing, with due attention to the regulation of fluid intake. An emptying contraction of the detrusor is initiated when the stimulus of stretch reaches an intensity sufficient to send an impulse along the afferent limb of the reflex arc. A useful means of bringing this to pass is by straining. This produces an increased intra-abdominal pressure, which is in turn transmitted to the bladder, there, the increased intravesical pressure produces the stretch stimulus, which sets off the voiding reflex. If the abdominal muscles are inadequate, a suitable belt may help. Tapping the abdominal wall, scratching the thigh, pinching the glans and other so-called "trigger" mechanisms are frequently used, but they are less physiologic and, generally, less dependable methods of stimulating bladder contraction. Direct manual pressure against the abdominal wall may reinforce the detrusor in the emptying of the bladder.

Before leaving this brief discussion of bladder function, one should note that other mechanisms have been described. Most recently, Mueller and Fleischer¹⁶ have demonstrated activity of voluntary muscles of the pelvic floor during the beginning of micturition, which they interpret as the initiating factor. It seems more probable, however, that such activity is of an auxiliary character.

Along with the care and training of the bladder, there are a number of collateral urologic problems affecting paraplegic patients. Renal calculi, of

less frequent occurrence than a few years ago, are occasionally encountered in patients returning after months or years at home. Pyonephrosis is a not uncommon complication. Treatment is not peculiar to paraplegia except, perhaps, for a greater than usual preoccupation with the conservation of renal tissue. Vesical calculi are treated by cystolitholapaxy without particular difficulty. Their occurrence or recurrence can often be averted by the establishment of good drainage, or by the use of suitable irrigating solutions when there is an indwelling catheter.

Chronic pyelonephritis is common. Bacteriuria is almost universal, but fortunately often exists without accompanying clinical evidence of infection, and with little or no pyuria. The organisms generally cultivated are the gram-negative bacilli, which are resistant to penicillin and respond but indifferently to the sulfonamides and streptomycin. For treatment over a long period, acidulation is useful when it can be achieved, with occasional courses of mandelic acid.

When renal infection becomes clinically apparent, appropriate investigation will reveal coexisting mechanical factors or structural changes in many cases. Notable among these is vesicoureteral reflux with hydroureter and hydronephrosis. The present view of the etiology of this condition is that it results not from neurogenic disturbance but from actual alteration of the ureterovesical orifice arising from chronic infection and distortion of the bladder wall.¹⁷ In the effort to correct this, two types of surgical approach have been employed. In one, the ureter is reimplanted into the bladder, in the other a complete lysis of the intravesical portion of the ureter is attempted. Too few cases have been treated so far to warrant any report on results.

Although hypertonicity of some degree is more common, hypotonic or even atonic bladders are encountered in paraplegic patients from time to time. On the basis of the assumption that this might be due to the physical state of the bladder wall itself, rather than the neurogenic factor, the size of the bladder was reduced, in 1 patient, by wide excision of the anterior wall. This man now has a normal capacity, can initiate micturition and has no residual urine. A second patient, subjected to a similar operation, has not yet reached the stage of trying to void, but already shows striking cystometric evidence of restored detrusor function.

Wherever there is extensive use of indwelling catheters, there will be a certain incidence of epididymitis, although meticulous technics may hold it down. Probably the best single prophylactic measure is the use of a small size catheter, preferably No. 16 Fr., and certainly not larger than No. 18 Fr. Prophylactic vasectomy is not desirable among

young men, many of whom retain sexual potency. After recurrent attacks of epididymitis, however, it is probable that the genital passages are effectively blocked, and that further exacerbation can best be prevented by epididymectomy. The chief danger of these recurring attacks is secondary involvement of the testicle and its ultimate destruction. One such case, which will be reported in detail at a later date, resulted in a fulminating, rapidly fatal septicemia. Vesicoureteral reflux, already mentioned, which is far more dangerous to health and life, seems to be slightly more frequent among patients who have had suprapubic cystostomies than among those who have not. Obviously, none of our present methods approaches perfection, but improving results justify the hope that continued effort and study may yet lead to further progress.

MUMPS COMPLICATED BY A PRECEDING MYELITIS*

Report of a Fatal Case

A CLEMENT SILVERMAN, M.D.†

SYRACUSE, NEW YORK

WHEN McKaig and Woltman,¹ of the Mayo Clinic, published their review of neurologic complications of mumps in 1934, they reported a case of transverse myelitis in a sixteen-year-old girl who was left with a complete flaccid atrophic paralysis below the second thoracic segment. Her spinal fluid, incidentally, showed no increase in cells in two tests during her illness. The authors found a similar case of mumps myelitis in the literature in a girl one year older. Wesselhoef² cites these 2 cases and adds a case of myelitis with recovery from the French literature. Bobeff and Petroff,³ of Sofia University, Bulgaria, report mumps myelitis with residua in a six-year-old girl and mention 5 other cases from the literature, remarking that it is significant that there is no mention of this complication in the seventeen-volume work of Bumke and

Foerster⁴ (1935-36). In the same year (1941) Donohue⁵ reviewed the pathology of mumps encephalitis. Among the 10 autopsies analyzed, besides his own case, there were 2 cases of myelitis in a man of thirty-eight with parotitis and orchitis, in the other, a woman of thirty-four, death occurred more than a year after quadriplegia had followed mumps. The anterior-horn cells of the cervical and lumbar enlargements showed marked atrophy and degeneration and the corresponding peripheral nerves demonstrated degeneration of their axis cylinders and disappearance of myelin. Donohue doubted, however, that this neuropathological picture had any etiologic relation to mumps. Van Rooyen and Rhodes⁶ refer to seven reports of mumps myelitis. Two cases with recovery are described by Lightwood⁷ and Church.⁸ When duplications are omitted, there are references to 12 recorded cases of myelitis, with 2 autopsies. It thus appears that myelitis is perhaps the rarest of the neurologic

involvements in mumps. It should be added, though, that undoubtedly many an unusual case occurs without being reported in the literature. In the Syracuse City Hospital, for example, a seven-year-old boy was admitted in 1938 with transverse myelitis following mumps. The case reported below is the second in almost nineteen years, among nearly 12,000 admissions for all causes*.

CASE REPORT

H G M., a 37-year-old physician, was admitted to City Hospital on June 19, 1947.

The day before, when making a call about noon, he found himself unable to shake down the thermometer readily. About 3 hours later he noticed in climbing stairs that the right leg seemed weak. In the evening while at a dinner he twice lost his balance and jokingly remarked that people might think he had been drinking. While making a call later that evening, he found it difficult to steer the car. He slept very little that night, being apprehensive that he was coming down with Landry's paralysis. Before morning he managed to go downstairs to his office to arrange as many of his affairs as possible because of his premonition. On the same morning he felt much weaker in both arms and legs, fell readily and had extreme difficulty in getting up, but could stand once he got on his feet. His wife took him to the hospital, and he managed to get out of the car and stand beside it, but when he attempted to go forward he fell and had to be lifted into a wheel chair.

He had always been in excellent health. In childhood he had had chicken pox, diphtheria, measles, rubella, scarlet fever and whooping cough but not mumps. A sister had had mumps, but he was away at the time, he thought. He had served as a medical officer with mountain troops in Italy during the war, he had had an attack of acute appendicitis there and had been operated upon uneventfully. For the past several weeks he had been working hard and felt tired out. There had recently been a number of cases of mumps in his area, and he had seen 2 cases with meningoencephalitis, 1 of which he had referred to the City Hospital 1 week before.

Physical examination showed an obviously anxious and apprehensive man, with no abnormal findings aside from the neurologic signs. There was no nuchal rigidity and no difficulty in swallowing. Respiratory movements appeared normal. There was generalized weakness in both upper and lower extremities. The biceps and triceps reflexes were diminished bilaterally. The right thigh was weaker than the left, but the reflexes were present. The abdominal reflexes were weakly present.

The temperature was 99.6°F by rectum, the pulse 64, and the respirations 20. The blood pressure was 125/75.

On an epidemiologic basis, the myelitis was considered due to mumps but without parotitis, and this diagnosis was offered the patient as affording a much better prognosis than Landry's paralysis.

A more complete neurologic examination was made later in the day and paralysis and paresis of most of the skeletal musculature were found. Superficial and deep sensation was not involved. There was no sign of meningeal irritation. The flexors of the neck were markedly weak. The cranial nerves were normal except for loss of the pharyngeal reflex.

Lumbar puncture yielded a clear spinal fluid without increased pressure containing 15 lymphocytes per cubic millimeter. The protein was 51, the sugar 79, and the chloride 750 mg per 100 cc. Spinal-fluid Wassermann, gum-mastic and colloidal-gold tests were negative.

Examination of the blood disclosed a red-cell count of 5,020,000 with a hemoglobin of 15.5 gm, and a white-cell count of 10,700, with 71 per cent neutrophils (10 per cent nonfilamented), 22 per cent lymphocytes, 6 per cent mononuclears and 1 per cent basophils. The urine was yellowish, clear and alkaline, with a specific gravity of 1.002. Tests for albumin and sugar were negative, and the sediment was

normal. Specimens of serum and spinal fluid were frozen and sent to the virus laboratory, Division of Laboratories and Research, New York State Department of Health.

During the next 2 days, the deep reflexes disappeared entirely, and the muscle weakness took the form of a complete quadriplegia. At no time was there a Babinski sign. The patient appeared more uncomfortable, restless and apprehensive. On June 21 bilateral parotid swelling appeared, somewhat greater on the right side. Next day he complained of pain in the legs but was able to move his feet a little and his shoulders very slightly. On the 5th day, he seemed more cheerful and somewhat encouraged. Hot packs to the muscles seemed to make him more comfortable. On this day the left parotid swelling was more prominent than the right.

On the next day he was more restless and apprehensive, having had a poor night. He was expectorating mucus

FIGURE 1 Section from the Parotid Gland, Showing Focal Lymphocytic Infiltration, Preservation of General Acinar Morphology and Pyknosis of Some Nuclei ($\times 800$)

but felt that he had more than he could bring up, and suction had to be performed frequently. The soft palate was normally movable, and there was no nasal twang and no fluid accumulation in the throat. He ate soft food and drank fluids without difficulty. In the night, however, he seemed unable to raise mucus, and his color was slightly dusky. Respiratory amplitude was unaffected. Oxygen was started by nasal catheter, and later that night the trachea was suctioned.

From this time on, the patient's condition and color continued poor, and he grew steadily worse. The temperature, which had previously remained normal, began to rise slightly. He was placed in an oxygen tent. Fluids were given intravenously, and also plasma and blood. Penicillin was started. Continual suctioning was required. On the evening of June 25 tracheotomy was performed, but the patient's color did not improve appreciably. He became confused and dis-

*Involvement of the central nervous system in mumps is a relatively common complication depending on the criteria employed for the diagnosis (whether on the basis of clinical findings, spinal fluid pleocytosis or chemical changes) and is usually quite benign so that fatal cases are extremely rare.

young men, many of whom retain sexual potency. After recurrent attacks of epididymitis, however, it is probable that the genital passages are effectively blocked, and that further exacerbation can best be prevented by epididymectomy. The chief danger of these recurring attacks is secondary involvement of the testicle and its ultimate destruction. One such case, which will be reported in detail at a later date, resulted in a fulminating, rapidly fatal septicemia. Vesicoureteral reflux, already mentioned, which is far more dangerous to health and life, seems to be slightly more frequent among patients who have had suprapubic cystostomies than among those who have not. Obviously, none of our present methods approaches perfection, but improving results justify the hope that continued effort and study may yet lead to further progress.

MUMPS COMPLICATED BY A PRECEDING MYELITIS*

Report of a Fatal Case

A CLEMENT SILVERMAN, M.D.†

SYRACUSE, NEW YORK

WHEN McKaig and Woltman,¹ of the Mayo Clinic, published their review of neurologic complications of mumps in 1934, they reported a case of transverse myelitis in a sixteen-year-old girl who was left with a complete flaccid atrophic paralysis below the second thoracic segment. Her spinal fluid, incidentally, showed no increase in cells in two tests during her illness. The authors found a similar case of mumps myelitis in the literature in a girl one year older. Wesselhoeft² cites these 2 cases and adds a case of myelitis with recovery from the French literature. Bobeff and Petroff,³ of Sofia University, Bulgaria, report mumps myelitis with residua in a six-year-old girl and mention 5 other cases from the literature, remarking that it is significant that there is no mention of this complication in the seventeen-volume work of Bumke and

Foerster⁴ (1935-36). In the same year (1941) Donohue⁵ reviewed the pathology of mumps encephalitis. Among the 10 autopsies analyzed, besides his own case, there were 2 cases of myelitis in a man of thirty-eight with parotitis and orchitis, no lesions in the central nervous system were found, in the other, a woman of thirty-four, death occurred more than a year after quadriplegia had followed mumps. The anterior-horn cells of the cervical and lumbar enlargements showed marked atrophy and degeneration and the corresponding peripheral nerves demonstrated degeneration of their axis cylinders and disappearance of myelin. Donohue doubted, however, that this neuropathological picture had any etiologic relation to mumps. Van Rooyen and Rhodes⁶ refer to seven reports of mumps myelitis. Two cases with recovery are described by Lightwood⁷ and Church.⁸ When duplications are omitted, there are references to 12 recorded cases of myelitis, with 2 autopsies. It thus appears that myelitis is perhaps the rarest of the neurologic

also the virus of lymphocytic choriomeningitis. Isolation of mumps virus was also attempted by inoculation of embryonated hen's eggs via the amniotic and yolk-sac routes. None of the animals showed any signs of illness, nor could the virus be isolated from the embryonated hen's eggs. Blind passages were done in both instances. The fourth-passage amniotic fluid from amniotically inoculated eggs was used as antigen in a complement fixation with known positive mumps serum. Normal amniotic fluid and fluid containing mumps virus were used as negative and positive controls respectively. This test, which is quite sensitive, failed to reveal mumps virus.

The serum specimen taken on June 19 was tested with mumps antigen in the complement-fixation test, and an insignificant degree of fixation found. The titer was approximately 16, whereas that of a negative control serum was 4 and a moderately high-titered serum was 128 in the same test.¹⁰

DISCUSSION

As has been indicated, very little autopsy material from cases of mumps has been adequately studied, and what changes have been described are not sufficiently specific for an etiologic diagnosis. So far as mumps myelitis is concerned, which more correctly is probably encephalomyelitis, the case reported above is probably the only one in which much detail is available, and even in this case the clinical history supplied the primary proof. Nevertheless, the histopathology of the parotid was similar to that described by Johnson and Goodpasture¹¹ in their experiments on monkeys. The changes in the brain and spinal cord were much like those previously described in the review by Donohue.⁵ The pathological changes in the lungs were not specific, but taken together give a picture like that described by Golden¹² in a review of 21 cases of atypical pneumonia. He noted the similar histopathological changes in pneumonia of influenza-virus etiology, of measles and of so-called atypical pneumonia, and grouped them as an acute interstitial pneumonitis. Incidentally, although Donohue's patient died of pulmonary involvement also, the report simply states "there were patchy and confluent areas of typical bronchopneumonia." In the literature on mumps there is no description of the disease in the lung such as that seen in our case.

The viral studies in this case apparently supply only negative results. It must be kept in mind, however, that certain viruses were excluded, and that failure to isolate mumps virus from the post-mortem tissues can have no bearing on the pathological diagnosis. In demyelinating meningoencephalitis one would not expect to isolate virus ordinarily. There was an interval of four days prior to inoculation, and this definitely reduces the chances of isolating mumps virus, which is labile. At the time the case was being studied, mumps virus could be readily isolated from saliva in the first two days of parotitis by inoculation of monkeys. In the meantime the virus has been isolated in eggs by Leymaster and Ward¹³ from the saliva of patients as late as six days after the onset of the disease.

In general, however, diagnostic dependence is placed upon the demonstration of complement-fixing antibodies. Although the blood on admission in the case reported above showed insignificant fixation, the patient's death precluded a subsequent sample, and it is regrettable that another blood specimen was not withdrawn at the time of death, for Enders¹⁴ has found that even in a week the antibodies may show a significant rise. But, in connection with complement fixation, new developments have come in the meantime. The

FIGURE 4. Section from the Lung, Showing Polymorphonuclear Exudate within the Bronchial Lumen, Sloughing of Bronchial Epithelium and Infiltration of Submucosa ($\times 115$)

The alveoli are relatively free of exudate, although scattered lymphocytes, mononuclears and plasma cells may be seen. The interstitial tissue also shows a mild infiltration by these cells.

adaptation of mumps virus to the chick embryo has revealed at least two serologically distinct complement-fixation antigens: the virus-bound or V antigen and the soluble or S antigen. The use of both antigens has permitted the early diagnosis of manifestations of mumps in the absence of parotitis, such as meningoencephalitis, since the finding of high levels of anti-S and of low or no titers of anti-V is considered diagnostically significant for the first few days of illness.¹⁵

There are only hypotheses concerning the cause of the central-nervous-system involvement of mumps

oriented. He could not sleep. The mucus became purulent. Death ensued on June 27.

Post-mortem examination, performed within 1 hour of death, revealed slight cyanosis of the ear lobes and lips. In the midline of the neck was a recent tracheotomy wound. There was swelling bilaterally in the region of the parotid gland, but the only abnormal gross finding was some edema of the gland itself and the surrounding tissue. Both lungs were somewhat heavier than normal, and both were deep purple and nonaerated, except for the upper portions of the upper lobes, which appeared normal. Most of the major

tis. The leptomeninges revealed some round-cell infiltration, insufficient to suggest an acute meningitis. Within the spinal cord there were early degenerative changes in the anterior-horn cells and marked perineuronal edema (Fig 2 and 3).

The pathological changes in the lungs consisted of an acute bronchitis and bronchiolitis, the lumens containing an exudate of leukocytes and the walls an infiltration of lymphocytes and mononuclear cells. The mucous membranes were partially necrotic. The alveoli were collapsed, but there was very little exudate within them. The cellular elements within the alveoli were predominantly lymphocytes and mononuclears, and there were also some of these within the alveolar walls (Fig 4). Cultures of the material within the bronchi yielded a few colonies of *Staphylococcus aureus*. Suctioned sputum obtained before death also yielded a few colonies of *Staph aureus*, and the direct smear showed many pus cells and an occasional gram-positive coccus.

Specimens of these tissues were also submitted to the head of the Department of Neurology at the University of Minnesota Medical School, who gave the following opinion:

The sections show minimal alterations. There are a few petechiae and some vascular congestion. The white matter demonstrates a mild diffuse gliosis and an occa-

FIGURE 2 Section from the Cerebral Cortex, Showing Longitudinal Section of a Small Vessel around Which There Is Some Demyelination and Lymphocytic Infiltration (x 800)

and minor bronchi were filled with a yellow, tenacious, elastic material, which was only moderately adherent to the bronchial walls. The bronchial mucosa showed some increase in vascularity. The pancreas and testes did not appear abnormal. The brain weighed 1330 gm and was marked by unusually prominent blood vessels. This increased vascularity also characterized the spinal cord. There was no gross evidence of exudate, although the spinal fluid was slightly cloudy. Portions of the brain and lungs were placed in 50 per cent glycerol for shipment to the state laboratory.

Microscopical examination demonstrated several areas of lymphocytic infiltration in the parotid gland. Some of the cells of the acini contained pyknotic nuclei, suggesting early necrosis, but for the most part the structure was well preserved. Numerous darkly stained areas were seen within the cytoplasm of the cells, these were tentatively identified as inclusion bodies, although their exact nature is not known (Fig 1).

The changes in the brain and spinal cord, although non-specific, were beyond question. Besides the diffuse dilatation of vessels, there was a mild perivascular demyelination and some proliferation of glial cells. Many vessels showed endothelial proliferation. The alterations were found primarily in the cortex and were indicative of encephali-

FIGURE 3 Section from the Anterior Horn of the Cervical Cord, Illustrating Marked Perineuronal Edema (x 480)

tion. A thin zone of perivascular myelin degeneration. The ganglion cells appear normal, however, a few within the brain stem show a few regressive changes. There is a mild endothelial proliferation in some of the cortical vessels. These changes are nonspecific but are suggestive of a mild encephalitic process.

Specimens of brain and lung in 50 per cent glycerol, received at the New York State laboratory on July 1, were used for inoculation of guinea pigs and mice in order to rule out the neurotropic viruses of the encephalitis group and

body or pulmonary neoplasm. Also, this may aid in better drainage and aeration of the diseased area. During bronchoscopy it may be feasible to aspirate the abscess cavity and to instill a suitable chemotherapeutic agent. Repeated bronchoscopic aspiration with instillation of penicillin directly into the abscess cavity as a form of definitive therapy has been widely used abroad but seems to be viewed with varying degrees of favor in the United States.^{3, 4, 7-9}

Adequate drainage of the abscess cavity is essential for successful medical treatment. One accomplishes postural drainage by inverting the patient with his head to the floor and with the body tilted so that the affected lung is uppermost. This should be done at least four times daily. Personal attention to determine the optimal position of the patient will frequently ensure good drainage when unsatisfactory results have been achieved previously. As a further aid to pulmonary drainage patients are taught to sleep without a pillow and with the foot of the bed elevated 20 to 30° during the course of therapy.

CHEMOTHERAPY

Multiple organisms are usually present, and abundant gram-negative organisms have been noted in the sputum after the administration of penicillin alone.¹⁰ For these reasons parenteral administration of both penicillin (50,000 to 100,000 units every three hours) and sulfadiazine or a mixture of sulfadiazine and sulfamerazine sufficient to maintain a blood level of approximately 12 mg per 100 cc is recommended. Local chemotherapy as penicillin aerosol, 40,000 units in 1 cc of isotonic sodium chloride, is administered with a vaponephrin nebulizer. A satisfactory aerosol spray is obtained by an oxygen flow of 5 to 7 liters per minute. A Y tube that diverts the air when the patient is not inhaling is used. No mechanism for condensing the expired air has been considered necessary. Aerosol therapy is carried out at four-hour intervals, preferably after postural drainage. In case organisms sensitive to streptomycin are isolated, streptomycin should be given in addition to penicillin both by aerosol and by the parenteral route. It has been suggested that the efficacy of aerosol can be enhanced by the addition of detergents such as agents of the quaternary ammonium series as zephiran chloride.¹¹ Such agents were not used in the cases reported below.

CASE REPORTS

CASE 1 A 35-year-old man was admitted to the respiratory ward of the hospital on February 22, 1947, with chills and fever that had followed recovery from a drunken stupor. The lung fields were clear, and he was treated symptomatically as a case of acute respiratory infection. At the end of 8 days the temperature was spiking daily to 104°F, and rales and consolidation were first noted in the right-upper-lung field. A roentgenogram of the chest revealed a wedge-shaped area

of consolidation to parenteral penicillin.^{10, 12} Some sur-
able radiolucent and the experience of seeing patients
consolidation. Sputum
hemolytic and green. S-
was given 50,000 units of penicillin in preparation for surgical
tion at 3-hour intervals. Because 3 cases reported above
dation numerous sputum specimens
fast bacilli, all were negative. The patient had
a febrile course, and 8 days after institution of
therapy a roentgenogram revealed an extensive
monic process, with a large central area of translu-
a questionable fluid level (Fig 1). He received
parenterally for 20 days, with no improvement. On
22 oral administration of sulfadiazine, penicillin aerosol, and
postural drainage were started. Within 5 days he became
afebrile, and a film of the chest showed diminished surrounding
reaction in the right-lateral-lung field and a definite abscess
cavity was no longer demonstrated. There was progressive
clearing of the lung fields, and only a small linear scar re-
mained. The sputum diminished and became negligible.
The sedimentation rate dropped from 50 mm to 4 mm per
hour (Wintrobe method). Therapy was continued for 6 weeks.
The patient was followed for an additional 2 months without
return of pulmonary symptoms or evidence of lung abscess
on repeated roentgenographic examinations.

CASE 2 A 42-year-old man was admitted to the hospital on April 13, 1947, with paroxysmal coughing and hemoptysis of 1 month's duration. The patient produced 500 cc. of pink, bloody sputum in 24 hours. His symptoms had begun 4 days after extraction of all his teeth under pentothal anesthesia. He had noted progressive dyspnea, pain in the right side of the chest and a weight loss of 17 lb. He was afebrile on admission. A roentgenogram of the chest revealed an abscess cavity in the right-lower-lung field. This cavity measured 4 by 5 cm in diameter and showed a fluid level (Fig 2). Bronchoscopic examination showed only inflammation in the right-lower-lobe bronchus. He was placed on the previously outlined course of therapy on April 16, and made a dramatic symptomatic and radiographic recovery. The daily sputum decreased from 500 cc. to 20 cc. within 2 days. Therapy was continued for a total of 24 days. Films of the chest taken 8 days after the institution of therapy showed disappearance of the previously seen abscess cavity. During the 24 days of therapy there was a rise in the hematocrit from 34 to 41 per cent. On completion of therapy the patient was discharged from the hospital without symptoms. He was followed for a period of 18 months, during which three roentgenographic examinations failed to reveal evidence of lung abscess and he had no pulmonary complaints.

CASE 3 A 26-year-old woman had had an infected molar extracted under local anesthesia on August 25, 1948. On August 30 fever and pleuritic pain in the left-lower-lung field developed. She was hospitalized 1 day later when the temperature was 101°F, the pulse 100, and the respirations 30. X-ray study of the chest revealed an area of increased density in the left lower lobe, with slight pleural thickening. The changes were considered indicative of pneumonia. The sputum was negative for hemolytic streptococci or pneumococci. The white-cell count was 12,000, with 85 per cent neutrophils. The patient was given 50,000 units of penicillin at 3-hour intervals and became afebrile and asymptomatic within 2 days. X-ray examination of the chest on September 7 showed slight clearing and she was discharged for follow-up study as an out-patient. Five days later she returned to the hospital with a recurrence of chills and fever. A film of the chest revealed an oval type of pneumonia in the area previously involved that was rather sharply circumscribed on the lateral film. This was again considered to be pneumonia although shut-off abscess or interlobar fluid was considered as a possible diagnosis. The temperature was 102.4°F, the pulse 110, and the respirations 26. Examination of the blood disclosed a white-cell count of 14,600, with 87 per cent neutrophils. Intramuscular administration of penicillin 50,000 units at 3-hour intervals, was started, with no improvement. Examinations of the sputum were negative for pneumococci, tuberculosis and hemolytic streptococci. The patient became progressively worse, the temperature spiking as high as 104.4°F, although she was receiving sulfadiazine in addition to penicillin. On September 17 she was placed in the head-down

and other common communicable diseases, and these are reviewed by Donohue⁵ and others^{2, 6, 16}

SUMMARY

A case of mumps myelitis with post-mortem studies, as well as viral studies, is presented, and the literature is briefly reviewed. This is probably the first case so fully reported. Symptoms and signs of myelitis preceded parotid swelling by three days. The pulmonary involvement, which was the cause of death, was consistent with viral disease, but whether it was caused by the primary virus is problematic. Newer diagnostic technics that were unavailable at the time the case was studied are discussed.

I am indebted to Dr. Max Newer, who had charge of the case, for permission to report it, to Drs. Alderman, Budgen, Rubenstein and Joseph Delmonico for consultation and assistance in handling various aspects of the case, to Dr. Irving Gordon, of the Division of Laboratories and Research, New York State Department of Health, for the viral studies, to Dr. Roemmelt and the Pathological Department of the Syracuse University College of Medicine for the autopsy and study of the sections, and to Dr. A. B. Baker, head of the Department of Neurology of the University of Minnesota Medical School for review of the sections.

MEDICAL TREATMENT OF ACUTE PULMONARY ABSCESS*

LIEUTENANT COLONEL WELDON J. WALKER, M.C., U.S.A.†

ANCON, CANAL ZONE

PLAN OF MEDICAL TREATMENT

Early diagnosis is most important. Lung abscess should be considered as a possible diagnosis in all "chronic" or "unresolved" pneumonias. Roentgenographic examination usually shows the characteristic area of pulmonary evacuation. A fluid level is generally present. However, about 5 per cent are shut off from bronchial drainage,⁵ do not manifest a fluid level and are difficult to differentiate from pneumonic infiltration. Lateral and oblique views are often needed for correct localization of the disease and to demonstrate lesions lying behind the heart. Identification of organisms in the sputum is important. However, multiple organisms are usually present, and in adults Smith⁶ has found anaerobic fusospirochetal organisms in 90 per cent of lung abscesses and believes these to be the principal etiologic agent. Abscesses secondary to pulmonary neoplasms, multiple embolic abscesses, primary bronchiectasis, tuberculosis and mycotic infections must be considered in the differential diagnosis and must be ruled out by appropriate studies.

Bronchoscopic examination is advised in all cases to establish the presence or absence of a foreign

IN TREATING patients with suppurative lung abscess the practitioner is often confused by the conflicting views expressed in current medical literature. Should such cases be treated surgically from the onset, with immediate drainage or resection,¹ or should they be followed with watchful expectancy because some will heal spontaneously?² It is my opinion that neither view is correct, that time is precious and that intensive and strenuous medical measures should be instituted immediately. If these procedures do not meet with rapid success, surgical intervention should not be delayed. When lung abscesses were diagnosed early, medical measures have led to recovery in as high as 80 to 90 per cent of cases.^{3, 4} When such methods do not result in cure they usually make the patient a better risk for surgical intervention. It is the purpose of this paper to outline in detail a proposed method of intensive medical therapy for acute lung abscess and to report 3 consecutive cases in which it has been successfully employed. Two of these were putrid lung abscesses, and the third appeared to be of the nonputrid post-pneumonic variety.

†Officer in charge, Colored Medical Section, Gorgas Hospital.

justifiable to consider all pulmonary abscesses as surgical problems from the onset. Intensive, comprehensive medical therapy of acute lung abscess will effect a cure in the majority of cases. This should include not only systemic penicillin but also systemic

refractive to parenteral penicillin.^{10 12} Some surgeons have had the experience of seeing patients with lung abscesses recover while they were receiving penicillin aerosol in preparation for surgical treatment.^{10 11} Two of the 3 cases reported above

C=film taken thirteen days later, after the abscess cavity is no longer evident. D=follow-up film taken two and a half months later — there is no evidence of pulmonary abscess.

sulfadiazine penicillin aerosol vigorous and frequent postural drainage bronchoscopic examination and the prompt use of streptomycin or other chemotherapeutic agents indicated. After penicillin aerosol therapy other authors have frequently noted recovery from pulmonary abscess in cases

failed to show improvement on parenteral administration of penicillin but healed almost immediately when a comprehensive course of therapy, including penicillin aerosol, was instituted. A shut-off abscess in which drainage through the bronchus cannot be accomplished is an indication for prompt sur-

and other common communicable diseases these are reviewed by Donohue⁶ and others.

SUMMARY

A case of mumps meningitis, as well as viral pneumonia, is reported. The literature is reviewed. This is the first case of mumps meningitis reported in the United States. Signs of mumps were present for three weeks. The patient was treated with penicillin and streptomycin. The patient continued to improve. The patient was discharged on October 9. After discharge from the hospital she was symptom free, and films of the chest 1 and 5 months later were clear.

—WALKER

wed progressive diminution in size. On October 1 it could no longer be demonstrated. Therapy was continued until October 9. After discharge from the hospital she was symptom free, and films of the chest 1 and 5 months later were clear.

FIGURE 1 Case 1

A=extensive pneumonia of the right lung, with an area of rarefaction suggestive of pulmonary abscess. B=overexposed film taken eight days later, demonstrating a pulmonary abscess with a fluid level. C=abscess cavity is no longer apparent, and there is beginning linear scar formation. D=follow-up film one and a half months later, showing residual linear scar. (All roentgenograms were reproduced by Madigan General Hospital Photographic Laboratory, Tacoma, Washington.)

choscopy, with essentially negative findings, 100,000 units of penicillin and 0.5 gm. of streptomycin in 5 cc. of isotonic sodium chloride were instilled into the left-lower-lobe bronchus. After this procedure she was started on a course of postural drainage and penicillin aerosol in addition to the systemic penicillin and sulfadiazine she was already receiving. She became afebrile within 2 days, and the abscess cavity

DISCUSSION

Since some authors have reported cure rates as high as 90 per cent^{3, 4} from the medical treatment of acute pulmonary abscess, it is no longer thought

MEDICAL PROGRESS

PSYCHIATRY

VERNON P WILLIAMS, M D *

BOSTON

IT IS gratifying to psychiatrists to see the importance of their specialty more and more clearly recognized and understood by medicine generally and by the public. The situation beginning with and since the war suggests that psychiatry may be approaching its heyday. The hope should be that its structure is or will be on foundations so sound that as time goes on it will not suffer through periods of questionable repute.

Even at present, it may be considered, a little uneasy, if there are signs of excessive enthusiasm or fervor in some directions. In speaking of the ominously revolutionary trends of today's social forces, Chisholm¹ says, "Without the extensive help of psychologists and psychiatrists it is quite probable that mankind will not long survive the fearful changes which are taking place." Perhaps this statement was calculatedly exhortative for the psychologists and psychiatrists, but if it was seriously meant for just what it says it seems wise for those addressed to decline modestly the honor of saving the race.

There is no evidence psychiatric or sociologic, that psychiatry has or can have the power and influence to shape man's course in the universe. Gregg,² to whom psychiatrists seem to listen with respect, writes, "Psychiatry can wave no magic wand and so obliterate powerful social forces and the conflicts that accompany enormously complicated social transitions, even if it has been fondly hoped or vaingloriously imputed to have such powers." Gregg's whole paper is an excellent, sympathetic evaluation of the place, possibilities and limitations of psychiatry. In an article written some time back, cautioning against unwarranted expectations from psychiatric treatment, the following remarks were made:

Reflecting on the frailties of human nature, one may well wonder whether religion or science presents the better road toward a better race. Psychiatry should play its part best by holding to a steady course in which it does not permit itself acclaim beyond its actual accomplishments.³

A more far-reaching development in psychiatry than any possible tendency toward assuming omnipotent capacities, a development that should be regarded more critically and objectively than it is in some quarters, is the body of Freudian psychoanalytic concepts. Today, psychoanalytic terms are so tossed about that the layman is likely to

assume that, in using them, he is referring to established truths, and even some psychiatrists are timid about challenging their authenticity, thinking that they as professional men may not be so well informed as they should be.

The valid accomplishments of psychoanalysis should not be discredited but psychiatry and people generally should not accept theoretic formulations and part-truths as scientific facts or whole truth. Menninger⁴ has written, "Actually, sex is the basic and all-pervasive motivation in life, and it must be understood for a healthy mentality." In reality, it has yet to be proved in regard to unmeasurable motivation that sex is any more basic than the forces or drives of self-preservation and self-development. To pronounce that sex alone is basic is to interpret human behavior in such manner as to substantiate a theory that one may want to believe but that is not supported by facts as we know them.

One may ask what difference it really makes whether or not sex, even in the broad, inclusive sense meant by psychoanalysis is considered the basic motivation. The importance of this is that the so-called interpretive or dynamic evolution in psychiatry has, by a number of causes, gained, assumed and maintains to an influential degree an authoritative position to which it is not entitled on scientific grounds. If psychoanalysis designates itself as a church, as a system of ideas and beliefs, that helps people to live more contentedly, more constructively, there is no quarrel between it and science, unless science itself has become headstrong.

To delineate further the authoritative position Menninger⁵ writes, "The misdirection of the aggressive drive is the basic cause of all maladjustment," and "The psychiatrist is convinced that emotional maturity can be reached only through a childhood experience in a situation that provides affection, good example, and security," and "Psychiatrists uniformly agree that the great majority of psychological cripples receive the injuries that predispose them to their crippled state in childhood, very often even in infancy."

Psychiatrists, if they have been well educated, and if they have not forgotten their education and if they retain the scientific attitude do not agree with such sweeping statements. They know there is little about which they can be sure, and they do

*Assistant psychiatrist, Massachusetts General Hospital

gical intervention. It is my belief that cases with satisfactory drainage that fail to show regression within four weeks should be treated surgically if repeated bacteriologic studies do not show organisms that require the use of additional chemotherapeutic agents.

Early diagnosis is the most important factor in determining the number of cases that will be cured by medical means. Few cures have resulted from medical treatment in chronic lung abscesses.⁶ These cases should ordinarily be treated by resection of the involved lung.^{13, 14} However, preoperative therapy similar to the treatment outlined for acute lung abscesses will result in improved preoperative condition of these patients and in an occasional medical cure. I agree with Scannell's¹⁵ suggestion that the therapy of lung abscess may largely resolve itself into a decision between medical treatment and extirpation.

Rubin¹⁶ has pointed out the most frequent cause of lung abscess to be an operative procedure on the oropharynx. Most observers believe putrid pulmonary abscess formation is due to aspiration of infected material, which lodges in a sublobar bronchus, producing a severe acute necrotizing inflammation. These are usually associated with chronic gingival infections.⁶ One of my cases followed multiple tooth extractions under general anesthesia, and another followed tooth extraction under local anesthesia. In both cases extractions were performed because of perialveolar abscess. There was no evidence that a particle of tooth had been aspirated in either case.

Postural drainage is a strenuous procedure and should be used with caution in the presence of cardiac disease or threatened pulmonary edema. However, it is undoubtedly one of the most important single therapeutic agents employed. The only complication from postural drainage in these cases was a small conjunctival hemorrhage.

SUMMARY AND CONCLUSIONS

It is proposed that a comprehensive plan for the medical treatment of acute pulmonary abscess should include both systemic penicillin and sulfadiazine, penicillin aerosol, adequate postural drain-

age, bronchoscopic examination and the prompt use of streptomycin or other chemotherapeutic agents indicated by bacteriologic study.

Three consecutive cases of acute pulmonary abscess were successfully treated in this manner. Two were putrid lung abscesses, and the third was of the nonputrid post-pneumonic variety. All cases showed complete disappearance of abscess cavity by roentgenographic examination within fourteen days of the institution of the therapy outlined. Two of the 3 patients had previously failed to improve under treatment for six and twenty days, respectively, with parenteral administration of penicillin.

It is believed that all suppurative lung abscesses, except for those shut off from bronchial communication, should receive such initial treatment with the expectation of cure in the majority of acute abscesses and better preparation of the chronic ones for pulmonary resection.

The view that all lung abscesses are surgical problems from the onset should be modified.

tility is present with no relation to the analyst or his attitudes there is still no reason to assume that it is a basic quality in the patient's personality or in the symptomatic configuration

In a magazine article Alexander¹³ refers to the two world wars and concurrent tyranny and cruelty as confirming "Freud's contention that behind a veneer of civilization man hides an asocial nucleus more destructive than the atomic nucleus he recently put to such devastating use." By "asocial nucleus" Alexander means an inborn destructive impulse or instinct, according to the context. Here again is an example of making the facts fit the theory—perhaps, to use the Freudian term, an example of repetition compulsion. To submit the chronologic and sociologic facts that two world wars have occurred within the past thirty-odd years, the fact that man tortures and persecutes man and the fact that man now has contrived a machine that could conceivably effect his own destruction—to present these facts as proof of an inborn impulse for destruction might connote superficial intelligence unless it is remembered that brilliant minds can be subject to circular or orbital thinking.

There is no proof whatever that, in either world war, men *generally* fought, destroyed, killed and maimed because of any deep impulse or drive—under the circumstances permissible or legalized—to do so. One might almost say that anyone knows that men fought because they had to, because their governments ordered them to and because of the consequences, personal and national, if they didn't. No doubt some men, some of the Germans, for example, in the recent war, zealously wanted to fight and had to make no effort to supplant any other primary desire, because they were so purely imbued with or indoctrinated in the master race ideology. We know that some men at least a few, earnestly desired to be "in it" because they did not want their "way of life," the democratic ideal, to be replaced by more palpable at least, tyranny or dictatorship. Also, no doubt, many men, gradually or latterly, became enthusiastic, more or less, because they did not want their way of life in practical obvious ways, to be changed for a probably indefinite period.

Most people are not particularly reflective, and therefore it may be reasonable to assume that the great majority of men who participated in the two world wars did so because they immediately thought there was no choice but to do so or because they were swept along by social forces that they did not actively oppose.

However, since men did as they did—destroyed, killed, caused untold anguish—it is asserted that they did so whether or not they consciously knew it, because they were impelled by one of two exclusively basic motivations. Except for those who would not be suitable for psychoanalysis, if all the people who took part in the world wars and all those

who did not take part, some professedly on principle, were to be psychoanalyzed—including in this number the rather timid man in a civilian-defense unit who was never confidently sure just how to apply the Thomas splint, and the many men and women who were considered unfit for active combat—successful analysis would reveal to the analyst and analyst that each individual was in it or not in it because he was motivated by a powerful instinct for destruction that, by most individuals, had not been consciously recognized or admitted.

If the presence and import of this instinct were not revealed by and to the analyst after an indeterminate lapse of time, resistance would still be obstructive, transference would not have been effected, the subject would be found unsatisfactory for analysis or the investigation would have to be terminated because of financial considerations.

It is submitted that a more credible explanation for the chaos that man creates for himself is a drive or motivation deeper and more pervasive than a supposed instinct for destruction. This force may be called self-interest. Most of the troubles into which man, singly and collectively, gets himself can be traced back to self-interest as a basic cause. From it can arise unlimited desire for power and acquiescence, and from its frustration can develop interpersonal animosity, hate, cruelty. On a larger scale, groups can be ruthless with each other, even to the extreme of employing atomic bombs, not primarily because of a desire to destroy but from a desire either to protect their interests or to increase their influence. Self-interest or self-protection, unfortunately and tragically for human welfare, is shortsighted and unenlightened, and there are few men who can think and feel beyond it if their particular Achilles heels have been hit. It might be called the greatest and too nearly universal human obsession. Its egotistic needs, cravings and demands are so powerful, subtle, devious and unrelenting—sometimes shrewdly calculating or compromising, consciously or unconsciously, and at other times catastrophically blundering for the individual—that it could conceivably propel to man's extinction. There is little wonder that Christianity considers it an important element in the doctrine of original sin.

The unsubstantiated theory of instinctive aggression or self-destruction serves self-interest neatly and subordinately. If the theory is accepted unquestioningly as fact, the acceptor is likely to excuse and exonerate himself for any hostility or hatred on the basis that, in all fairness, he can hardly be asked or required to oppose successfully in thought or action a force as intrinsic as the action of his heart. He may even get to thinking that it is not only all right but healthy to exhibit hostility. However, this is not the place for a disquisition on the theory of self-interest and self-protection.

not overlook or discard the importance of constitution and heredity in human behavior

In a critical essay on what he calls "autistic trends in psychiatric thinking," Freyhan⁶ nicely analyses the dangers of overemphasis on the dynamic interpretation of psychiatric or personality disorders

Positivistic ideologies have produced a tendency either to underestimate or even to ignore the necessity of appraising constitutional and hereditary aspects of psychiatry. It is hardly an exaggeration to state that these factors are actually taboo in general psychiatric discussions. The often heard argument that investigations in these fields have failed to yield tangible results is not in accord with facts and must be regarded as another symptom of autistic rationalization

Farther along, he states "Bartemeier stressed the importance which Freud attributed to the hereditary predisposition and warned that one-sided preoccupation with environmental factors is not at all in accordance with Freud's total theory of psychopathogenesis." Freyhan's paper is worth reading in its entirety by anyone who may wonder if he has become a little unbalanced on the subject of psychiatric etiology

It may be recalled that Freud⁷ himself stated his position as follows

The expectation that we shall be able to cure all neurotic symptoms is, I suspect, derived from the lay belief that neuroses are entirely superfluous things which have no right whatever to exist. As a matter of fact they are serious, constitutionally determined affections, which are seldom restricted to a few outbreaks, but make themselves felt as a rule over long periods of life, or even throughout its entire extent. Our analytic experience that we can influence them to a far-reaching degree, if we can get hold of the historical precipitating causes and the incidental accessory factors, has made us neglect the constitutional factor in our therapeutic practice. And we are in fact powerless to deal with it, but in our theory we ought always to bear it in mind. In any case, the complete inaccessibility of the psychoses to analytic therapy should, in view of their close relationship to the neuroses, moderate our optimism in regard to the latter. The therapeutic efficiency of psychoanalysis is limited by a whole series of important factors, which can scarcely be dealt with at all

Psychoanalysis may demur, saying that, even in post-Freudian development, it makes no assertion that it effects cures in whatever problems it undertakes, that it is essentially an investigative discipline and as such is interested in disclosing the fundamental structure of psychopathology. Undoubtedly the interest in psychopathology is genuine, but there is an inclination to make too wide application of theoretic psychologic or psychobiologic nuclei, sets, complexes or so-called instinctive drives. One example is the maintaining that in a large percentage of cases of alcoholism an etiologic factor is a latent or conscious homosexual conflict. Another is the assumption that the same conflict is etiologically present in the paranoid states. One paper, suggesting that healthy, scientific doubt and objectivity are not swamped, is the report of a study, by Klein and Horowitz,⁸ of 80 patients who had diagnoses of paranoid state

or schizophrenia, paranoid type. These writers conclude

The paranoid mechanism cannot be explained solely by homosexual conflict despite the convincing evidence of its pertinence in certain cases. It is so obvious in the cases in which it occurs, that the limits of its application are all the more surprising. If the relationship of homosexuality to the paranoid mechanism is assumed to be invariable, other important considerations will be neglected

The actual existence in human nature of an inherent, instinctive drive of destructiveness or aggressiveness, expressed by hostility toward various parts of the environment, is too much taken for granted by some psychiatrists. Freud⁹ wrote, "The bit of truth behind all this — one so eagerly denied — is that men are not gentle, friendly creatures wishing for love, who simply defend themselves if they are attacked, but that a powerful measure of desire for aggression has to be reckoned as part of their instinctual endowment." Horney¹⁰ quotes Freud as saying, "Hatred is at the bottom of all the relations of affection and love between human beings."

Not all investigators agree that an instinct of aggression is an essential part of the warp and woof of our structure. Horney¹⁰ says, "The theory of a destruction instinct is not only unsubstantiated, not only contradictory to facts, but is positively harmful in its implications." She sees aggression and hostility as reactions provoked by frustration

If we want to injure or to kill, we do so because we are or feel endangered, humiliated, abused, because we are or feel rejected and treated unjustly, because we are or feel interfered with in wishes which are of vital importance to us. That is, if we wish to destroy, it is in order to defend our safety or our happiness or what appears to us as such. Generally speaking, it is for the sake of life and not for the sake of destruction

From her comprehensive experience with children, Bender¹¹ is not able to accept the Freudian theories of aggression and hostility. She thinks this emphasis is one-sided and "has led our students of child psychology astray." She believes "the child has an inherent capacity or drive for normality" and "that aggression in childhood is a symptom complex resulting from deprivations which are caused by developmental discrepancies in the total personality structure such that the constructive patterned drives for action in the child find inadequate means of satisfaction and result in amplification or disorganization of the drives into hostile or destructive aggression."

That psychiatrists, like other people, may get what they are looking for is suggested by Johnson,¹² in his critique of psychoanalysis. He contends that "free" association, in the analytic procedure, is not really free, that the patient is influenced by the analyst's conceptions and ideational systems. I propose, somewhat comparably, that if the analyst is looking for hostility or evidence of aggression for example, he, by his own attitude, may easily create it or augment it in the patient. Even if hos-

his system may carry a hallmark of truth that is not merited. An impressive example of this is the extent to which the concept of the Oedipus complex has made a place in psychiatric and common thought.

Sears,¹⁶ in a report of objective investigations of psychoanalytic concepts, writes, "Freud assumed the Oedipus relationship to exist universally, and while other investigators have found instances of it, no indications of a universal cross-sex parental preference have been discovered in either children or adults." The universality of this complex had previously been refuted by Westermarck¹⁷ for those who had ears to hear and eyes to see.

The same propensity for generalization occurs in relation to various other Freudian concepts. Again, Sears¹⁶ remarks

Several sources of evidence indicate, however, that Freud seriously overestimated the frequency of the castration complex and the importance of childhood sex aggressions. The castration complex, like theories of the origin of babies, is a function of the kinds of information children have. Freud's tendency to rely on cultural universals—which do not exist—has led him to postulate universal attitudes and complexes that can be demonstrated in but a part of the population.

A dominant defect of the Freudian psychoanalytic discipline is to take or mistake a part for the whole, unwarrantedly to assert that a complex or a number of complexes, which may or may not be present, are causative in human behavior.

With no depreciation of the significant work done by psychoanalysis, Sears¹⁶ concludes

The experiments and observations examined in this report stand testimony that few investigators feel free to accept Freud's statements at face value. The reason lies in the same factor that makes psychoanalysis a bad science—its method. Psychoanalysis relies upon techniques that do not admit of the repetition of observation, that have no self-evident or denotative validity, and that are tinctured to an unknown degree with the observer's own suggestions. These difficulties may not seriously interfere with therapy, but when the method is used for uncovering psychological facts that are required to have objective validity it simply fails.

This does not mean that all psychoanalytic findings are false, but it does mean that other methods must be sought for their critical evaluation and validation.

The purpose of psychotherapy, including psychoanalytic therapy, is to relieve, as far as possible, the person from burdensome and handicapping behavior or thinking that prevents him from being reasonably contented. This would supposedly mean enabling the patient to get along better not only with himself but also with others. It is an almost everyday truism that the two most essential ingredients of this prescription are forbearance and tolerance, being more patient with and understanding of oneself and others, with various qualifications. In therapy, psychoanalysis surely would not state that it is interested only in the individual and has no concern with interpersonal relationships, for the two are interwoven and inseparable. If tolerance, forbearance and consideration for the other person

are essential, analytic therapy must be, or should be, working toward a fairly close semblance of the Christian meaning of love.

In a recent radio broadcast (Town Meeting, on April 26), Karl Menninger, the co-author of *Love Against Hate*, concluded that we should love rather than hate. A previous reference in this paper alluded to another authority,¹⁸ although not a scientist, who said much the same thing some years ago. If psychoanalysis, in its endeavors, finds reason to emphasize what Christianity has been advocating for centuries it seems that it and religion are not so disparate as some have feared. However, it should be said that to date there is no evidence that students, professors or advocates of psychoanalysis or persons who have gone through the expensive, time-consuming, analytic treatment are any more forbearing, considerate or loving of their fellow men than other people.

Earlier in this paper there was reference to the importance of constitutional and hereditary determinants in psychiatric illness. In discussing psychosomatic states, Freyhan¹⁹ again emphasizes that these constituents should not be disregarded. He writes that some psychiatrists, with their interest in psychogenic factors, seem to forget that the somatic side of the alliance exists. This could be thought odd if the very name of the partnership is kept in mind. Freyhan says, "We are told again and again that it is the conflict between powerful dependent needs and the aggressive solution of this conflict in the face of frustration of the receiving tendencies which is of crucial importance for the development of peptic ulcers." The sentence construction is somewhat confused, but the meaning is clear enough. He continues

Psychosomatic thinking can neither be based on well meant sociologic platitudes nor on outdated analytical concepts.

Unfortunately most psychiatrists pay little attention to modern genetic and constitutional researches, in fact the term "constitution" is practically taboo and still associated with therapeutic nihilism and reactionary organic-mindedness.

Daniels²⁰ gives a nod to the somatic side but apparently thinks the psycho more important. To quote him

One of the misconceptions in connection with the inclusion of psychic factors in the causation of physical disease is that these factors are made to represent "the whole reason" for the condition. Such an impression may arise from the overenthusiasm of the investigator or the misinterpretation of the critics.

The personality of these patients is vulnerable because of the persistence of emotional immaturities with marked inner dependence on a parental figure, generally the mother.

Somewhat belatedly Alexander²¹ allows a place for heredity in neurotic development. He writes

At the beginning of the Freudian era the importance of childhood experiences was discovered and claimed as the cause of neurosis. Gradually we have come to recognize at least three sets of factors which together in varying de-

As indicated previously, psychiatrists should be concerned with the trend in professional and popular thinking that allows some psychoanalysts, under the formidable aegis of Freud's power, and, in turn, many laymen to believe that they have an indisputable grasp of the truth. Any prominent, articulate physician, in expressing his opinions, may have a subtle or direct influence, which may be understood as signifying authority. In a recent review of Freud's last, posthumous book, *An Outline of Psychoanalysis*, Binger¹⁴ writes, referring to what Freud has written, "Here is the truth, he says, in effect — my truth — take it or leave it." Then Binger continues

By and large, modern, educated, Western men and women have chosen to take it. They either deny it with passion and vehemence, thereby, in a sense, acknowledging its threat, or they accept it. But they seldom understand it. In spite of clichés about "complexes," "fixations" and all the rest, they seldom comprehend the deep metaphysical and moral implications, the epic and heroic portrayal of life as a titanic struggle between two instincts — Love and Death.

At least to me, Binger implies that Freud was probably right. When he suggests that people who do not agree with Freud's truth may be acknowledging its threat, the implication seems to be that opposition to an idea weighs in favor of the rightness of the idea — that people rarely oppose untruth. Although it may be presumed that, in general, people do not like to face facts if they hurt personally, it also may be presumed that some people do not like to accept as fact ideas or pronouncements that are not supported by irrefutable or probably irrefutable data. Surely there are scientists who, without passion or vehemence, find no reason to accept Freud's dictums. Parenthetically, I happen to know some analysts who, with passion and vehemence, defend Freudian dictums. If by "threat," Binger did not mean "truth" or what is probable, but had in mind the dictionary definition, "an expression of an intention to inflict evil or injury to another," it may not be singularly aberrant of some Western men and women to deny Freud's truth.

Again, in stating that although, by and large, modern, educated Western men and women have accepted Freud's explanation, they "seldom comprehend the deep metaphysical and moral implications," Binger seems to be producing overtones, at least, of reverence, of awesome respect for Freud's ideas, if not for the man himself. Binger is aware of Freud's intransigence, and Freud¹⁵ leaves no doubt about it, with his introductory statement, "The teachings of psychoanalysis are based upon an incalculable number of observations and experiences, and no one who has not repeated those observations upon himself or upon others is in a position to arrive at an independent judgment of it."

"Deep metaphysical and moral implications" of various theories of man's whence and whither have been considered by poets, philosophers and

schoolboys ever since man became reflective. To give uncritical credence to Freud's theories is — to borrow phraseology from Winston Churchill* — something "up with which" scientists should not put

Psychiatrists know, or should know, that suggestibility is a characteristic of the human species, not excluding themselves. Through the ages men of forceful personality have influenced thousands of people to believe in them and in the rightness of their ideas. In our own time the phenomenon of Hitler can scarcely be overlooked.

As quoted above, Freud said, "Hatred is at the bottom of all the relations of affection and love between human beings." In analyzing the Christian commandment, "Thou shalt love thy neighbour as thyself," Freud⁹ has written

We will adopt a naïve attitude towards it, as if we were meeting it for the first time. Thereupon we find ourselves unable to suppress a feeling of astonishment, as at something unnatural. Why should we do this? What good is it to us? Above all, how can we do such a thing? How could it possibly be done? If the high-sounding ordinance had run, "Love thy neighbor as thy neighbor loves thee," I should not take objection to it. And there is a second commandment that seems to me even more incomprehensible, and arouses still stronger opposition in me. It is "Love thine enemies." I imagine now I hear a voice gravely adjuring me "Just because thy neighbour is not worthy of thy love, is probably full of enmity towards thee, thou shouldst love him as thyself." I then perceive the case to be like that of *Credo quia absurdum*.

This is very enlightening. A man who found hate behind all human affection and who found incomprehensible the import of loving one's neighbor as oneself, and who thought it absurd to believe that a man can love his enemies, is looked upon as having new and surpassing powers for penetrating personality. Probably Freud had such powers in some respects, but the powers were surely limited if he did not know and understand that there have been some men who loved and that there are some men who do love their enemies. Apparently it was not included in Freud's gifts of insight and analysis to conceive this kind of love. It seems to be a likely hypothesis that within Freud's own make-up there was a large measure of hatred, which led him to find the same quality in his patients.

This emphasis is of serious intent and does not spring from a carping or retributive attitude. The sway of Freud and his followers is great. Scientific, psychiatric progress is and will be impeded unless psychiatrists, more generally than at present, try to hold to an objective evaluation of their observations, beyond personal interest. If the founder of psychoanalysis is accepted and applauded as an incontrovertible authority, any ideas that he propounded and any ideas that are proposed under

*Winston Churchill had submitted a draft of an important wartime speech to the British Foreign Office for comment. The draft was returned with no comment whatever on content, but where he had ended a sentence with a preposition a Foreign Office purist had cared the preposition into its stuffy grammatical position. At this the Prime Minister flew into a lather. To the offending purist he despatched a note, "This is the type of agent p. lantry," read the note, "up with which I will no put!" (*Reader's Digest*, May 1949).

CASE 35331

PRESENTATION OF CASE

First admission A fifty-one-year-old salesman was admitted to the hospital because of a cough productive of blood-streaked sputum.

He had been in good health until three months prior to admission when he first noticed streaks of bright-red blood in his sputum upon coughing. These episodes occurred about every other day for a week and then cleared. One week later he had another bout of hemorrhage that seemed to come from the mouth and nose and lasted ten minutes. Since that time he had had a number of episodes of coughing with blood-streaked sputum, unrelated to any particular activity. The patient stated that he had had a chronic cough for many years, usually associated with smoking. He denied a recent change in the character of the cough or any increase in the amount of sputum. He had lost 15 pounds in weight during the year prior to admission but had regained 10 pounds in the three-month period before coming to the hospital. One evening four months before entry, he had a chill and vomited some dark material. Later that night he awoke with pains in the mid-back. He had no cough or hemoptysis at this time, however, and felt well the next morning. Two weeks later an abscessed tooth was removed under a local anesthetic. The patient stated that for two months before admission he had noticed that one artificial tooth was missing. During the month prior to entry he had mild pain in the right arm and shoulder when he raised his arm to put on his coat. There was no history of wheezing, dyspnea, cyanosis or further chills. His appetite was good.

The past history was otherwise noncontributory except for a tonsillectomy and an attack of "rheumatism" thirty-six and twenty-eight years before, respectively. Seven years before admission the patient was taken into the Army for a nine-month

period. His father and a brother had died of tuberculosis some thirty-five years before.

Physical examination revealed a well developed and nourished man in no acute distress. The heart and lungs were normal, and aside from a small 1-cm cyst under the right eyelid, no abnormalities were recognized.

The temperature, pulse and respirations were normal.

The urine was normal. Examination of the blood showed a hemoglobin of 14.4 gm and a white-cell count of 9400, with 56 per cent neutrophils, 35 per cent lymphocytes, 3 per cent monocytes and 6 per cent eosinophils.

A roentgenogram of the chest showed a patchy area of increased density in the superior segment of the right lower lobe extending from the hilus to the pleural surface laterally and posteriorly. Above the area of increased density was an area of normal density surrounded by a thin rim of increased density. This was thought possibly to be a chance crossing of vascular shadows or a very thin-walled cavity. No foreign bodies were recognized.

Bronchoscopy was negative except for slight reddening of the right main bronchial tree. A cytologic smear of the sputum was negative.

In the hospital the patient's condition remained unchanged. A second history taken five days after admission established a different chronology to the points of progress of his disease as follows: an episode of grippe or cold four months before admission; a tooth extraction two weeks later; a dental plate inserted one week later and his first bout of hemoptysis some time thereafter. Three separate examinations of the sputum failed to reveal acid-fast bacilli. A culture of the sputum grew out abundant alpha-hemolytic streptococci and a few beta-hemolytic streptococci.

It was believed that the lesion in the right lower lobe was probably an abscess, and the patient was discharged on the sixth hospital day.

Second admission (about eleven weeks later) In the interval the patient had been well and free of hemoptysis until ten days before entry when he again coughed up small amounts of blood-streaked sputum. At this time, he also noted a temperature of 101°F, excessive sweating and a pleuritic type of pain in the lower portion of the right chest. The pain disappeared after two days.

The findings on physical and laboratory examination were essentially unchanged. A roentgenogram of the chest showed the density in the right lower lobe to be somewhat larger and its margin less distinct than on the previous study. There were also linear markings of increased prominence extending from the abnormal density to the hilus. There was a small fluid level within the density. There was a questionable small amount of fluid within the right pleural cavity.

gress contribute to neurotic disease. These factors are heredity, early experiences of life, and actual difficulties. A patient with poor hereditary equipment may be destined to develop neurosis no matter what happens to him.

Recognition of other factors besides early life experiences may have come gradually to some of the analysts, but they have been considered as possibilities and probabilities by many psychiatrists long before some groups of psychoanalysts admitted their possibly determining presence. If analysis takes credit for discovering hereditary, constitutional and immediately present difficulties in the patient's life situation as elements to be assessed in neurotic reactions, it gives itself the position of arbiter in psychiatry, which position actually it does not hold.

In the paper previously cited, Gregg² makes several references to the subject of heredity. He writes, "Until the medical profession sees its patients as having genetic as well as psychological and somatic histories we shall have to admit our professional ignorance of heredity and the only fragmentary knowledge as yet revealed as one of the primary remediable limitations of psychiatry." He says further, "Because among human beings an observer seldom can expect to outlive both the child and the child of the child he observes, the hereditary factors affecting mental defect, disease, or disorder and the components of personality, temperament, and patterns of behavior have received but little of the attention they deserve."

Gregg concludes, "Though it is still early to know how to think about human heredity there are few subjects more potent for the prevention of psychiatric defect, disorder, and susceptibility to strain. I cannot escape the conviction that we must begin to seek the way to find the truths of human inheritance."

No psychiatrist with therapeutic sense and sensibility will find his interest in or enthusiasm for

therapy dampened because of therapeutic limitations. In spite of its tragedies, psychiatry has, beyond estimable measure, mitigated human suffering. Until man, through religion or science, is reborn, psychiatry should hold a contributory and honored province and it will hold it best through a becoming admixture of humility.

CASE 35331

PRESENTATION OF CASE

First admission A fifty-one-year-old salesman was admitted to the hospital because of a cough productive of blood-streaked sputum.

He had been in good health until three months prior to admission, when he first noticed streaks of bright-red blood in his sputum upon coughing. These episodes occurred about every other day for a week and then cleared. One week later he had another bout of hemorrhage that seemed to come from the mouth and nose and lasted ten minutes. Since that time he had had a number of episodes of coughing with blood-streaked sputum, unrelated to any particular activity. The patient stated that he had had a chronic cough for many years, usually associated with smoking. He denied a recent change in the character of the cough or any increase in the amount of sputum. He had lost 15 pounds in weight during the year prior to admission but had regained 10 pounds in the three-month period before coming to the hospital. One evening, four months before entry, he had a chill and vomited some dark material. Later that night he awoke with pains in the mid-back. He had no cough or hemoptysis at this time, however, and felt well the next morning. Two weeks later an abscessed tooth was removed under a local anesthetic. The patient stated that for two months before admission he had noticed that one artificial tooth was missing. During the month prior to entry he had mild pain in the right arm and shoulder when he raised his arm to put on his coat. There was no history of wheezing, dyspnea, cyanosis or further chills. His appetite was good.

The past history was otherwise noncontributory except for a tonsillectomy and an attack of "rheumatism" thirty-six and twenty-eight years before, respectively. Seven years before admission the patient was taken into the Army for a nine-month

period. His father and a brother had died of tuberculosis some thirty-five years before.

Physical examination revealed a well developed and nourished man in no acute distress. The heart and lungs were normal, and aside from a small 1-cm cyst under the right eyelid, no abnormalities were recognized.

The temperature, pulse and respirations were normal.

The urine was normal. Examination of the blood showed a hemoglobin of 14.4 gm and a white-cell count of 9400, with 56 per cent neutrophils, 35 per cent lymphocytes, 3 per cent monocytes and 6 per cent eosinophils.

A roentgenogram of the chest showed a patchy area of increased density in the superior segment of the right lower lobe extending from the hilus to the pleural surface laterally and posteriorly. Above the area of increased density was an area of normal density surrounded by a thin rim of increased density. This was thought possibly to be a chance crossing of vascular shadows or a very thin-walled cavity. No foreign bodies were recognized.

Bronchoscopy was negative except for slight reddening of the right main bronchial tree. A cytologic smear of the sputum was negative.

In the hospital the patient's condition remained unchanged. A second history taken five days after admission established a different chronology to the points of progress of his disease as follows: an episode of gripe or cold four months before admission, a tooth extraction two weeks later, a dental plate inserted one week later and his first bout of hemoptysis some time thereafter. Three separate examinations of the sputum failed to reveal acid-fast bacilli. A culture of the sputum grew out abundant alpha-hemolytic streptococci and a few beta-hemolytic streptococci.

It was believed that the lesion in the right lower lobe was probably an abscess, and the patient was discharged on the sixth hospital day.

Second admission (about eleven weeks later) In the interval the patient had been well and free of hemoptysis until ten days before entry when he again coughed up small amounts of blood-streaked sputum. At this time he also noted a temperature of 101°F, excessive sweating and a pleuritic type of pain in the lower portion of the right chest. The pain disappeared after two days.

The findings on physical and laboratory examination were essentially unchanged. A roentgenogram of the chest showed the density in the right lower lobe to be somewhat larger and its margin less distinct than on the previous study. There were also linear markings of increased prominence extending from the abnormal density to the hilus. There was a small fluid level within the density. There was a questionable small amount of fluid within the right pleural cavity.

On the eighth hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR CARROLL C MILLER The history of this case, the presumptive diagnosis and the subsequent surgical disposition seem to revolve around three salient features hemoptysis, signs and symptoms of pulmonary infection and x-ray findings in the right lower lobe. The causes of hemoptysis in the lower respiratory tract, in a broad sense, may be classified as follows for a brief review foreign body, with or without subsequent necrosis, infections, with necrosis and erosion of blood vessels (and most important, among these infections, are abscess, bronchiectasis, pneumonia or pneumonitis and tuberculosis), tumors, either benign or malignant, primary or metastatic—the latter rarely cause or produce hemoptysis, infarct, and finally heart disease and congenital anomalies of the vascular tree

In view of the x-ray findings in this case many of these can be omitted from discussion. Recurrent hemoptysis seems to direct our consideration into certain definite channels. Intermittence of hemoptysis is not uncommon, especially in tumors or infectious processes, since the growth of tissue in a tumor or the alternate necrosis and focal thrombosis associated with infection may account for freedom from bleeding for varying periods

This man had no previous history of any trouble in his lungs as far as we know, but he did have probable exposure to tuberculosis, since his father and a brother had died of tuberculosis many years previously. This fact may or may not have a bearing on the diagnosis

I was prompted to wonder why he spent such a short time in the Army, nine months, according to the record, in about 1942. But no explanation is given for that

He had had marked weight change—he lost 15 pounds in the year before admission, but this was before he became ill. During the period when his symptoms and signs were developing he had regained 10 pounds of that weight loss. So these details do not contribute in any definite way to the making of a diagnosis

The significant data in the history are that four months before his first admission he had an episode of chills and vomiting, two weeks later, a tooth extraction was done, and then the fitting of a dental plate, and, curiously enough, two months prior to admission he noticed that one of the artificial teeth was missing. This might be called the saga of the missing tooth. Following this episode he began to have blood streaks in his sputum. There are some details that I have tended to pass over. The arm and shoulder pain seem to have had no striking relation to the present illness. They may very well have been bursitis or tendinitis or some

recrudescence of rheumatism of many years past. The absence of wheezing noted in the protocol is important in indicating no significant obstruction to the bronchial tree. The culture as reported is not of importance. We have been tending in recent years to put less and less stress on sputum culture reports in conditions such as this, because, invariably, there is a mixed infection and only when we are interested in outlining a plan of antibiotic therapy are we interested in knowing exactly what the organisms are. In other words, in cases such as this with a relatively small, limited focus, the bacteriology does not significantly contribute to the making of a diagnosis except of course in the presence of tuberculosis

In recapitulation, therefore, we have an episode of infection, chill and mid-back pain and then later hemoptysis. X-ray studies at that time showed segmental density with a question of cavity in this area. The location of this cavity is emphasized in the protocol with the description of an area of normal density surrounded by a thin rim of increased density. This is above the segmental density noted to be in the superior segment of the right lower lobe. Then the patient had a respite from symptoms and signs for three months and went on to recrudescence, with fever and chest pain of the pleuritic type. I postulate that he had an infectious process, which may have been the simple uncomplicated lung abscess type, associated with adjacent pneumonitis. There may have been a foreign body present. The radiologist tells me that some artificial teeth may not be radio-opaque, and therefore may not be seen in a plain film of the chest. There may have been a tuberculoma present, which had not been discovered previously. This may have broken down, emptied and involved the segment in an inflammatory reaction. Many tuberculomas contain live tubercle bacilli, and the presumption is that some would have been seen in the sputum, but their absence is not conclusive evidence against the diagnosis of tuberculosis. Likewise, the absence of cancer cells in the Papanicolaou smear is not definite evidence against cancer of the lung. However, our laboratory has now a very high percentage of positive results by this method. The chronic pneumonitis of the type reviewed by Dr Waddell* recently in this hospital may have a small cavity, 4 out of 10 cases that he has reported had cavities up to 1.5 cm in diameter. I am not able to go any farther with a definite diagnosis than to say that this was a chronic lung abscess, but I still would like to think that there probably was a foreign body in the form of a missing tooth in this area. Tuberculosis may have been found or, likewise, a focus of cancer. I was given the opportunity to study the x-ray films before I presented this case, and was impressed by the ap-

*Waddell: W. R. Sniffen, R. C. and Sweet, R. H. Chronic interstitial pneumonitis: report of 10 cases showing chronic interstitial pneumonitis and unusual deposits of cholesterol. *J. Thoracic Surg.* (in press)

pearance, as Dr Wyman may point out, of an increase in the width of the wall of the cavity noted in the serial films. May we see the films, Dr Wyman?

DR STANLEY M. WYMAN: The lesion described lies in the right mid-chest laterally. There is streaky density extending from the lesion to the hilus. In the lateral view this is seen to lie far posteriorly as recorded, probably in the superior segment of the right lower lobe. The first films do not show conclusively a cavity. The examination, done approximately two months later, shows a more discrete and somewhat larger area of infiltration, with an apparent fluid level, and, as Dr Miller suggests, a thickened wall above. This is seen in the lateral view, and the fluid level is best demonstrated in the lateral projection. One month later the infiltration in the right lower lobe is still larger, and the spot films at this time demonstrate clearly a central area of rarefaction with a probable, small fluid level. The apparent increase in the size of the wall superiorly is seen. Whether this represents actual intrinsic increase in the size of the wall or apparent increase because of atelectasis of adjacent lung, it is impossible to say. Well demonstrated is the pleuritic reaction adjacent to this area of disease. I think it is worth noting that the inner wall of the cavity seems to be smooth, not shaggy or nodular.

DR MILLER: That feature is somewhat against the presence of cancer because in such lesions as we have seen previously there is some irregularity or nodularity of the lining shadow. I might add that the likelihood that this was tuberculoma is very slim. Certainly, in this early picture I would expect a more discrete, clearly rounded, denser shadow if this were a tuberculoma. The possibility of cancer, however, is borne out by several facts. The tendency for density to extend down toward the hilus of the lobe indicates either extension of the process or metastatic obstruction of that segmental bronchus. Also, the fact that, following the return of symptoms three months after the patient was in the hospital the first time, the surgeon elected to proceed with this operation suggests his suspicion of the presence of cancer. Certainly, cancer must be suspected strongly in all these cases, and operation should be done first to make a diagnosis, secondly to cure the patient, if possible, and thirdly, to relieve him of these annoying, terrifying symptoms if possible. I would still, however, persist in my first diagnosis of a nonspecific abscess, with pneumonitis, possibly due to the retention of foreign body, chiefly because of the roentgenographic evidence and the nature of the hemoptysis and of the patient's clinical course.

DR E. B. BENEDICT: I doubt if this was foreign body. If it was a tooth, it probably was the patient's own tooth, and that ought to show by x-ray study or by bronchoscopy. I certainly agree with Dr Miller that the important thing is to treat it as if

it were carcinoma until proved otherwise by explorative thoracotomy.

DR JOHN G. SCANNELL: That is what the patient thought too. He was convinced from the beginning that he had a cancer, and it was difficult not to agree with him. However, when we first saw him, the possibility of an inhaled tooth became apparent and we bronchoscoped him with that in mind. At this time it did appear that the parenchymal shadow was improving, and it was the decision of Dr Churchill and Dr King to follow him closely and meanwhile rule out tuberculosis, which seemed the most likely diagnosis. After three months he began to spit blood again, and with the chance of carcinoma now even more likely, exploration was advised. He was operated on by Dr Churchill, whose pre-operative diagnosis was either carcinoma or tuberculosis.

When the chest was opened the disease process was obviously limited to the superior segment of the right lower lobe. There was no free fluid. The involved segment was firm and injected, but there was no discrete mass and no puckering of the pleura so often seen with carcinoma. On gross inspection the lesion appeared to be benign, in keeping with the diagnosis that Dr Miller has chosen. A segmental resection was done, largely as a biopsy, and inspection of the lesion in the gross indicated that that was all that was necessary. We could find no foreign body, and no apparent cause for the disease.

CLINICAL DIAGNOSIS

Carcinoma?
Tuberculosis?

DR MILLER'S DIAGNOSES

Chronic lung abscess (with foreign body?)
Carcinoma?
Tuberculosis?

ANATOMICAL DIAGNOSIS

Abscess of lung

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: We found a small abscess cavity, 8 mm in diameter, which was surrounded by an area of chronic pneumonitis. There was no foreign body identified. The histologic appearance of the wall of the abscess cavity was characteristic of an organized infectious process of the lung, with many fibrous plugs in the respiratory bronchioles and some in the alveoli. It did not show any marked degree of the lipoid reaction that is seen in many cases with similar histories and similar x-ray findings.

Our diagnosis was a simple abscess of the lung.

DR DANIEL S. ELLIS: Do you ever see such an abscess following an infarct?

DR MALLORY: Almost never, I would say, in the human being. In animal experiments Dr Cutler produced them many times.

CASE 35332

PRESENTATION OF CASE

A thirty-three-year-old woman entered the hospital because of a lump in the right breast

Approximately two years before admission she first noticed an indurated area in the inferior aspect of her right breast. She experienced sharp pain in this area just before the onset of each menstrual period. It changed little in size until she became pregnant sixteen months before entry, when it increased, only to subside again when she miscarried at two and a half months. Ten months before entry she again became pregnant with coincident enlargement of the areas of induration, which again regressed when she miscarried at six weeks. Six months before entry she again became pregnant, and the area markedly increased in size as the pregnancy progressed. She was occasionally bothered by sharp pains in the breast but had no bleeding or discharge from the nipple.

The past history and system review were negative.

Physical examination showed a well developed and well nourished woman in no distress. Inferior to the right nipple occupying most of both lower quadrants of the breast was an ill defined, firm mass within the breast about the size of a tennis ball. There was no retraction of the overlying skin or nipple. The uterus was enlarged to a size consistent with a six-month pregnancy. The remainder of the physical examination was negative.

The temperature was 98.8°F, the pulse 80, and the respirations 20. The blood pressure was 130 systolic, 80 diastolic.

The routine urine examination was negative.

On the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. GORDON A. DONALDSON: The one thread running through this history that catches my eye is the fact that this patient of thirty-three had a tumor that was sensitive to the hormones associated with pregnancy. I am going to grasp at that fact to rule out other indurated tumors that might cause the physical features of the tumor described — namely, a low-grade type of abscess, fat necrosis, tuberculosis, sarcoid disease and so forth — and will limit the discussion to chronic mastitis, the fibroadenoma group of tumors and perhaps cancer. I think it is very unlikely that this was cancer or

sarcoma — although there are others here who certainly could elaborate on that point at greater length — because I doubt very much whether a cancer of the breast could be as responsive as this particular tumor was to hormonal factors associated with pregnancy. We do know that some types of cancer change during pregnancy, or increase in size, but I doubt if we should entertain such a diagnosis very strongly in this particular case. So we boil it down to a fibroadenoma with perhaps cystic changes or cystic mastitis itself.

There are several additional points that would be helpful in the history — namely, the condition of the other breast, the presence or absence of axillary changes and a few notes regarding what was seen on simple inspection of the breast. We have been taught that a good deal can be gained by simple inspection of the breast with the patient's hands behind the head, first while sitting up and then lying down. It is also said that 90 per cent of tumors that can be picked up by inspection in such positions prove to be malignant. I think this tumor would probably have been seen on inspection. I doubt very much, however, whether we should consider it malignant. I also doubt if this represented a pericanalicular fibroadenoma, since the tumor was too large. We are therefore left with the possibility of intraductal papilloma, with cystic change. We have a history of no nipple discharge, which would be against such a tumor. The fact that this lesion was indurated and also painful, producing pain with the menses and with pregnancy, is greatly in favor of a mastitic process.

So the presence of a large, indurated tumor, changing under hormonal stimulation and producing pain, leads me to believe that chronic cystic mastitis in some form is probably the best diagnosis.

DR. RICHARD H. WALLACE: I first saw this patient in my office two years before admission, when she said that she had noticed a small lump in her breast two years previously that had not changed in size during the interval. She sought professional advice because she had planned to be married two days later. At that time it measured 3 cm., and was firm. I had the impression that it was a benign tumor, but I advised her to have it removed. We talked over the matter of pregnancy, since the patient stated that she hoped to start a family promptly. I suggested that she have the tumor removed in the near future. I saw her the second

time eighteen months later. She had been married in the meantime, had become pregnant and had miscarried. During the pregnancy the tumor definitely increased in size and subsequently decreased. At the next visit, I should say that the tumor had increased slightly in size, but she again declined surgery because she was leaving the country by air the next day. I saw her again when she was six months' pregnant, at which time she had a tumor measuring 16 cm in greatest diameter. It was more like two tennis balls stuck together, in lobular fashion. The tumor was visible in all positions. The opposite breast was normal for a six months' pregnancy. The axilla had no palpable lymph nodes, and there was considerable dependent edema of the skin in the lower portion of the breast, presumably on a mechanical basis.

DR JOSEPH C AUB: Was it cystic?

DR WALLACE: No cystic areas could be demonstrated.

DR TRACY B MALLORY: Dr Nathanson, would you like to comment?

DR IRA T NATHANSON: These manifestations of the tumor in question are seldom seen because lesions of this type are often removed before pregnancy or are not necessarily responsive to hormonal stimuli. This lesion responded on three occasions during pregnancy in apparently the same fashion as the breast. It also became sensitive and, I judge, enlarged in the pre-menstruum. This probably paralleled an increase in activity of the breast, which appears to be dependent upon hormonal fluctuations during the menstrual cycle. Likewise, during pregnancy and lactation these endocrine stimuli

are increased. I have seen a few other patients who have refused operation on the first occasion. In one case, the patient had a tumor the size of a large grapefruit, which regressed to about 3 cm during involution of the breast following the first pregnancy and lactation. Here, again, the tumor responded to hormonal stimulation during a second pregnancy.

This brings up one point about which there is disagreement — that is, whether fibroadenomas are true tumors or merely represent localized manifestations of breast tissue that are unusually reactive. The latter opinion is one that is held by some of us here.

CLINICAL DIAGNOSIS

Sarcoma of breast?

DR DONALDSON'S DIAGNOSIS

Chronic cystic mastitis

ANATOMICAL DIAGNOSIS

Lactating fibroadenoma of breast

PATHOLOGICAL DISCUSSION

DR MALLORY: The tumor removed was large and kidney shaped, as Dr Wallace has already brought out. The microscopical structure was that of a typical adenofibroma, but the epithelial elements were unusually active, and a large proportion of them, as well as the surrounding normal breast tissue, showed evidence of secretion as one would expect at six months' pregnancy.

CASE 35332

PRESENTATION OF CASE

A thirty-three-year-old woman entered the hospital because of a lump in the right breast

Approximately two years before admission she first noticed an indurated area in the inferior aspect of her right breast. She experienced sharp pain in this area just before the onset of each menstrual period. It changed little in size until she became pregnant sixteen months before entry, when it increased, only to subside again when she miscarried at two and a half months. Ten months before entry she again became pregnant with coincident enlargement of the areas of induration, which again regressed when she miscarried at six weeks. Six months before entry she again became pregnant, and the area markedly increased in size as the pregnancy progressed. She was occasionally bothered by sharp pains in the breast but had no bleeding or discharge from the nipple.

The past history and system review were negative.

Physical examination showed a well developed and well nourished woman in no distress. Inferior to the right nipple occupying most of both lower quadrants of the breast was an ill defined, firm mass within the breast about the size of a tennis ball. There was no retraction of the overlying skin or nipple. The uterus was enlarged to a size consistent with a six-month pregnancy. The remainder of the physical examination was negative.

The temperature was 98.8°F, the pulse 80, and the respirations 20. The blood pressure was 130 systolic, 80 diastolic.

The routine urine examination was negative.

On the second hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR GORDON A. DONALDSON: The one thread running through this history that catches my eye is the fact that this patient of thirty-three had a tumor that was sensitive to the hormones associated with pregnancy. I am going to grasp at that fact to rule out other indurated tumors that might cause the physical features of the tumor described — namely, a low-grade type of abscess, fat necrosis, tuberculosis, sarcoid disease and so forth — and will limit the discussion to chronic mastitis, the fibroadenoma group of tumors and perhaps cancer. I think it is very unlikely that this was cancer or

sarcoma — although there are others here who certainly could elaborate on that point at greater length — because I doubt very much whether a cancer of the breast could be as responsive as this particular tumor was to hormonal factors associated with pregnancy. We do know that some types of cancer change during pregnancy, or increase in size, but I doubt if we should entertain such a diagnosis very strongly in this particular case. So we boil it down to a fibroadenoma with perhaps cystic changes or cystic mastitis itself.

There are several additional points that would be helpful in the history — namely, the condition of the other breast, the presence or absence of axillary changes and a few notes regarding what was seen on simple inspection of the breast. We have been taught that a good deal can be gained by simple inspection of the breast with the patient's hands behind the head, first while sitting up and then lying down. It is also said that 90 per cent of tumors that can be picked up by inspection in such positions prove to be malignant. I think this tumor would probably have been seen on inspection. I doubt very much, however, whether we should consider it malignant. I also doubt if this represented a pericanalicular fibroadenoma, since the tumor was too large. We are therefore left with the possibility of intraductal papilloma, with cystic change. We have a history of no nipple discharge, which would be against such a tumor. The fact that this lesion was indurated and also painful, producing pain with the menses and with pregnancy, is greatly in favor of a mastitic process.

So the presence of a large, indurated tumor, changing under hormonal stimulation and producing pain, leads me to believe that chronic cystic mastitis in some form is probably the best diagnosis.

DR RICHARD H. WALLACE: I first saw this patient in my office two years before admission, when she said that she had noticed a small lump in her breast two years previously that had not changed in size during the interval. She sought professional advice because she had planned to be married two days later. At that time it measured 3 cm, and was firm. I had the impression that it was a benign tumor, but I advised her to have it removed. We talked over the matter of pregnancy, since the patient stated that she hoped to start a family promptly. I suggested that she have the tumor removed in the near future. I saw her the second

is nowhere so crucial as in this situation. That which is lost — whether it is whole blood, water, chloride or protein — should be replaced as accurately as possible, no more and no less. The lavish hand must be stayed if the patient is to be given his best chance of survival. Digitalis and restorative drugs cannot set right the wrong done by poor judgment regarding intravenous fluid therapy.

Many other therapeutic points could be mentioned. There remains, however, no substitute in a therapeutic dilemma of this magnitude for sound clinical knowledge and observation, and a thorough grounding in the physiologic principles underlying rational cardiovascular therapy.

POLIOMYELITIS—A DIAGNOSTIC PROBLEM

WITH the arrival of the poliomyelitis season, the problem of diagnosis again comes to the fore. Little difficulty is, of course, encountered with the cases exhibiting frank paralysis. In recent years, however, physicians have been attempting to recognize the nonparalytic form of the disease. Here the diagnostic problem becomes exceedingly difficult.

The differences of opinion that arise among groups of physicians were illustrated in an incident in Massachusetts in 1948. In the central portion of the State two communities side by side were having illnesses probably due to the same virus. In one, the pattern was to call the illness lymphocytic choriomeningitis—in the other, meningitis of undetermined origin. A short distance away a large group of cases occurred in another community where it may well have been that the same virus was operating. In this community the cases were called poliomyelitis.

In the absence of a laboratory diagnostic test, it is impossible to say which of the three groups of physicians correctly diagnosed the condition. The absence of paralysis in all the cases makes the diagnosis of poliomyelitis quite unlikely. This incident emphasizes the ease with which an incorrect diagnosis can be made in such borderline cases.

Poliomyelitis started early in Massachusetts in 1949. Whether this foretells an epidemic year or whether it merely indicates an early poliomyelitis

season cannot be determined until the trend of the disease in the immediate future can be ascertained. The comparatively higher prevalence since 1944 may indicate that the disease is spread over a period of four or five years instead of having a short one-year outbreak. The return to the normal proportion of two-thirds paralytic to one-third non-paralytic cases may indicate that the confusing virus prevalent in 1948 may be of less importance this year. Last year two-thirds of the diagnosed cases were nonparalytic.

ROSEOLA

ONE of the commonest diagnostic errors that occur in pediatric practice is the failure to differentiate roseola infantum (or exanthem subitum) from other febrile affections—especially pharyngitis, measles and German measles. The excellent paper by Berenberg, Wright and Janeway that appears elsewhere in this issue of the *Journal* provides a critical analysis of this somewhat enigmatic disease and should be of service in reminding the practitioner of the possibility of its occurrence.

The febrile eruptive disorder called roseola is of relatively recent identification in the literature, Zahorsky having first described it in 1910, and attached to it its common name. It had, however, been known and so-called by practitioners prior to this literary event. Perpetuation of the designation was unfortunate for accurate diagnosis, in that the name as well as the appearance of the rash brings to mind both rubeola and rubella. Further knowledge of the potentialities of the viral infections in general has increased the importance of its differential diagnosis.

Roseola, on account of its ordinarily mild nature, is not commonly seen in hospital practice—181 cases were observed at the Children's and Infants' hospitals in the ten-year period from 1937 to 1947. This group, however, representing more than mildly sick patients, indicates the latent possibilities for mischief that exist with almost any viral infection.

Roseola may occur at any time of the year, although its periods of highest incidence are in late spring and mid-autumn. Ninety-five per cent of

CARDIAC CONTRAINDICATIONS TO SURGICAL PROCEDURES

THE patient with heart disease who develops a disorder requiring surgical intervention often presents a taxing therapeutic dilemma to the attending physician. To withhold surgery may be almost certainly fatal, but to permit a major surgical procedure in the face of serious heart disease may seem equally foolhardy. The surgeon and the anesthetist have done a great deal to minimize the danger of operation to patients with heart disease. Improvements in surgical technics, anesthetic agents and insistence on the constant maintenance of an adequate supply of oxygen represent major advances in the direction of safe operation for cardiac patients. But the dilemma still recurs, although less frequently than was formerly the case.

From the point of view of the cardiologist, heart disease itself is not necessarily a contraindication

Nevertheless, many patients who need elective and occasionally some who need emergency operations are denied proper surgical treatment merely because of the presence of valvular, hypertensive or some other type of heart disease. On this basis alone, such a stand may not be justified.

When the time factor is not of prime importance, the cardiac contraindications to elective procedures may be defined with fair precision. In this situation, there are at least five such contraindications: cardiac decompensation, acute myocardial infarction, acute, paroxysmal arrhythmias, active myocarditis or pericarditis and bacterial endocarditis. In cases of cardiac decompensation, whatever the etiology of the heart disease, compensation should be restored before elective operation is attempted. Likewise, an acute myocardial infarct must be allowed to heal before the procedure is carried out. Paroxysmal arrhythmias must be abolished or controlled. Active involvement of the myocardium or pericardium, whether rheumatic or due to some other etiologic agent, should be allowed to subside before operation is undertaken. Bacterial endocarditis is such a serious disease in itself that no elective surgical procedure should be considered until it is controlled by appropriate treatment with antibiotics. Very severe coronary vascular disease with angina pectoris may constitute another contraindication. Milder grades of the disease seldom do so, although the patient should be protected with extreme care from oxygen lack and blood loss during operation.

In surgical emergencies, such as acute intestinal obstruction and common-duct stone, one may be driven to ignore the cardiac contraindications. Chances may have to be taken to serve the patient's best interests. Even in such desperate situations it is usually possible to minimize the risk to the patient if the surgeon, cardiologist and anesthetist pool their knowledge and deal with the problem along physiologic lines. In addition to proper use of cardiac drugs, the patient's tolerance for intravenous fluids must not be exceeded. Intravenous administration of saline solution is often a deadly agent in cardiac patients and seldom has a logical place in their preoperative or postoperative management. The principle of fluid replacement therapy

is nowhere so crucial as in this situation. That which is lost—whether it is whole blood, water, chloride or protein—should be replaced as accurately as possible, no more and no less. The lavish hand must be stayed if the patient is to be given his best chance of survival. Digitalis and restorative drugs cannot set right the wrong done by poor judgment regarding intravenous fluid therapy.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON LEGISLATION

One of the most controversial issues before the Massachusetts General Court during the current legislative session was the Cash Sickness Compensation Bill. This bill was strongly supported and strongly opposed. Hearings were stormed and noisy.

The bill provided for a state-operated monopolistic compulsory cash sickness program for workers. Major argument hinged chiefly upon this proviso. A spokesman for the CIO stated before committee, "I think this is legislation that is long overdue. It happens to be in the Governor's message and I want to say very emphatically that if we don't get a state fund program, we are on record that we will accept no cash sickness at all. We will ask the legislature to defeat it if the committee doesn't report it favorably, and we will ask the Governor to veto it because the workers want no part of profiteering in human misery and sickness."

The Cash Sickness Compensation Bill was finally defeated by the narrow margin of three votes. The problem is now slated for study by a commission. The brief filed by direction of the Committee on Legislation of the Massachusetts Medical Society follows:

STATEMENT OF THE MASSACHUSETTS MEDICAL SOCIETY ON HOUSE NO. 2591, THE CASH SICKNESS COMPENSATION BILL, FOR THE COMMITTEE ON WAYS AND MEANS OF THE MASSACHUSETTS GENERAL COURT

The Massachusetts Medical Society finds itself not in complete agreement with House No. 2591, the Cash Sickness Compensation Bill, as it now stands.

This bill has been carefully studied by the Society since printed copies became available. It is not our purpose to single out points we would praise or condemn as private citizens and voters interested in the broad problems of the public health.

Our principal function as a medical society is to view this, as all other legislation pertaining to health, as working for or against the best possible standards of medical progress and the mental and physical health of the public.

Under this bill as drawn the physician is held responsible for the medical operation of the sickness compensation plan. The claimant for benefits must have filed a physician's certificate (Sec. 7 [a] [4]) and, "if directed to do so by the director, [shall] have submitted to a medical examination for the purpose of determining his sickness" (*Idem*).

In practice this requirement would charge practicing physicians not only with administrative responsibilities but with underwriting responsibility as well. E. H. O'Connor, managing director, Insurance Economics System of America, has stated, "As these state plans begin to expand, as is evident from legislative bills introduced in Rhode Island, California and New Jersey, more benefits will be paid and the cash sickness benefits of a state fund must be protected. It will naturally follow that

the state will be forced to set up rules and regulations for the certification of claimants."

Solvency of a state fund might be protected if it were possible to determine ability to work in all instances through promulgation of rules and regulations and the application of existing medical knowledge. Every physician knows there are many instances where it is absolutely impossible to determine medically whether a person is or is not able to work.

This is particularly true in cases of mental illness. The definition of "sickness" (Sec. 3 [m]) contains the words

"because of his physical or mental condition, he is unable to perform his regular or customary work." It was stated in Federal Security Administrator Oscar R. Ewing's report to the President that from 30 to 50 per cent of all persons consulting doctors have complaints due at least in part to emotional disorders. For the evaluation of these complaints it is stated 4500 psychiatrists are available in this country where some 15,000 are needed.

From the point of view of the medical profession, charged with the responsibility of certification and professional administration, it cannot be too much emphasized that this program concerns itself essentially with temporary disability. Experience has shown the importance of adequate administrative control for the successful operation of such plans. We wish to stress that the evaluation of conditions of temporary disability depends upon factors which are at best 50 per cent subjective.

The dangers to the solvency of the cash sickness compensation fund from malingering have been recognized by the architects of this bill. "He [the director] shall also publicize the potential results of malingering" (Section 18). In view of what has been said above concerning the subjective factors of temporary disability it must be made clearly apparent that merely designating the physician as the policeman is not the answer. There are no magic tests for the evaluation of purely subjective symptoms.

For the 6750 physician fellows of the Massachusetts Medical Society we feel we can promise full co-operation within the code of ethics of the Society and of the American Medical Association within the limitations previously noted. We point out, however, that no criteria for diagnoses are established within the bill and there is no provision for a medical advisory board to assist in this and other important functions under the bill.

The bill defines a "physician" (Sec. 3 [r]) as "an individual licensed to practice medicine or dentistry under the laws of this or any other state." For some 2500 physicians licensed to practice in Massachusetts the added ethical controls over fellows of the Massachusetts Medical Society are absent. For them the basic legal controls of malpractice laws are the limits to which they can be held.

Under Section 8 *Claims and Appeals* (c) provision is made for calling as an expert witness any medical adviser appointed by the director. There is no provision made for establishing the qualifications of such experts.

In view of the tremendous responsibilities placed upon the individual physician and upon the medical profession in the administration of this plan, we seriously question the absence of the physician's voice in the setup for administrative control.

This defect is the more notable since Section 12 *Penalties* states, "Any person convicted of a violation of any provision of this chapter or of a violation of any order, rule or regulation of the director or of the division made under the authority of any provision of this chapter, the punishment for which is not otherwise provided, shall be punished by a fine of not more than fifty dollars for the first offense, and for any subsequent offense within a period of two years immediately following his final conviction of a like offense by a court of the Commonwealth, shall be punished by a fine of not less than fifty dollars nor more than two hundred dollars, or by imprisonment for not more than two years, or both."

Respectfully submitted for the President and fellows of the Massachusetts Medical Society

JOHN F. CONLIN, M.D.
Director of Medical Information and Education

cases occur between the ages of six months and three years. Its most characteristic feature is that the rose-pink, somewhat morbilliform rash occurs almost invariably at the time of defervescence from a three-day to five-day fever, and actually, unlike the eruptions of most of the acute exanthemata, marks the beginning of convalescence. Attention to this one striking characteristic would prevent many a mistaken diagnosis.

No specific viral agent has yet been isolated, and the relatively rare spread by contact, with occasional apparent instances of unusually long incubation periods, marks roseola as a disease of "poorly defined communicability." Despite its almost invariably good prognosis, roseola may nevertheless occur as a severe infection with convulsions as its commonest complication. This is suggestive of the group of viral diseases that require continued study in view of the insidiousness of the attack and the remoteness of the consequences.

WASHINGTON REPORT ON THE MEDICAL SCIENCES

THE idea of the temple on the hill dates back, no doubt, to the earliest sacrificial altar. The geographic elevation placed the worshiper a little nearer to the object of his veneration, in addition to which his devotions could more easily be observed by the less exalted members of the tribe. The Tower of Babel provides an extreme example of carrying a good thing too far.

The custom, once sacred, has become secular as well. The modern state places its seat of government also on a hill, probably to make it appear a little nearer to the source of divine guidance, perhaps also to catch the cooling breezes that have been so conspicuous by their absence from Capitol Hill this summer.

Capitol Hill seems to generate heat, in fact, rather than escape it. The case of socialized medicine, which had been under control for a number of weeks, burst into flame again in late July with the introduction of President Truman's reorganization plan, including the creation of a Department of Welfare. With the country heading toward the footing of

a welfare state, this would presumably become the tail that wags the dog. In its defense Mr. Ewing, according to *Washington Report on the Medical Sciences*, of July 25, "disavowed charges that have been made that elevation of FSA to Department rank would bring new prestige and new powers that would be employed for all they were worth toward achievement of national compulsory health insurance." The plan, he stated, contains nothing that would add to the authority he already possesses, to which he subjoined rather naïvely, "Besides, the President has not told me he intends to appoint me as the new Secretary."

A Department of Health with a physician as Secretary is desired in many quarters instead of a Department of Welfare and is being supported by the American Medical Association. The question whether the Secretary should be of necessity a physician can be argued. Secretaries of War and of the Navy have usually been laymen, and better so, the Secretary of Labor is not commonly a laborer, although the country has always breathed more freely when the Secretary of State was a statesman.

Sometimes half a loaf, buttered, is better than a whole loaf, dry.

Veterans Administrator Carl R. Gray, Jr., has finally conceded that Dr. Paul B. Magnuson, chief medical director, should be in direct charge of the Administration's medical program. He has acknowledged in writing, also according to *Washington Report on the Medical Sciences*, that the sole purpose of operating veterans hospitals is the care and treatment of patients.

An opinion is prevalent, that a physician, who is a writer, must be a poor practitioner, therefore, an author, however distinguished, cannot compete with a neighbor who may not be able to write his mother tongue grammatically. In other words, a man cannot be successful in both, and hence the public sentiment, to an extraordinary extent, is decidedly in favor of a physician who does not trouble himself with books, or divert his mind from the grave consideration of visiting patients, by interesting himself in the details of science.

AUREOMYCIN IN THE TREATMENT OF PNEUMONIA IN INFANTS AND CHILDREN*

BENNETT OLSHAKER, M.D.,† SIDNEY ROSS, M.D.,‡ ADRIAN RECINOS, JR., M.D.,§ AND
ELLSWORTH TWIBLE, M.D.†

WASHINGTON, D. C.

AUREOMYCIN is an antibiotic derived from a strain of *Streptomyces aureofaciens*. The drug has been found to have a wide antibacterial spectrum against gram-positive and gram-negative organisms. In addition, it has been found to be effective against rickettsia as well as certain viruses chiefly of the lymphogranuloma-venereum-psittacosis group.¹ In man therapeutic doses up to 60 mg per kilogram of body weight per day given orally have not been associated with toxic manifestations except for occasional nausea, vomiting and diarrhea. These symptoms have been transient and do not contraindicate or prevent continuation of therapy.

Aureomycin is absorbed readily after oral administration, and the maximum rate of excretion in the urine occurs between four and eight hours after the dose.² Thus, an interval between doses of four to six hours can be considered optimum. The oral route is the preferable mode of administration. Intramuscular injection is accompanied by local pain and sometimes induration and tenderness. Aureomycin may be given intravenously, but this method of administration was not employed in our series.

A study to evaluate the efficacy of aureomycin[®] in the treatment of pneumonia in infants and children was instituted in January, 1949. This investigation was prompted by the observation that the drug is effective against the bacteria most frequently responsible for pneumonia and by published reports of its value in the treatment of atypical viral pneumonia.^{3, 4} It has been found that strains of pneumococcus, streptococcus and *Hae-*

mophilus influenzae are almost completely inhibited by aureomycin in concentrations of 1 microgm per cubic centimeter or less.⁵ Such a blood concentration is readily obtained with therapeutic doses of the drug. Recently, Schoenbach and Brer² and Finland and his co-workers⁴ reported small series of cases of primary atypical pneumonia that responded well to aureomycin. This constitutes the first indication of any effective antibiotic agent in viral pneumonia, all previous therapy having been found to be ineffective.

Thus, aureomycin, because of its versatility, seems to be an extremely valuable agent in the treatment of pneumonia. A drug that is effective against both viruses and bacteria embraces a considerably larger antimicrobial range than either sulfadiazine or penicillin (or both combined) and should be effective against the vast majority of pneumonias encountered in the pediatric age group.

MATERIALS AND METHODS

In view of these considerations it was believed that aureomycin warranted a clinical trial. To this end, a special pneumonia ward was set up at the Children's Hospital. So far as possible consecutive patients who had clinical and roentgenologic evidence of pneumonia were treated with aureomycin on admission to the hospital. These patients either had not received previous therapy or had not been benefited by chemotherapy or antibiotics.

A uniform plan of study was employed in all cases, including nasopharyngeal and blood cultures, blood counts, x-ray examination of the chest, agglutinins for streptococcus MG and cold hemagglutinins at periodic intervals during the course of therapy. Nearly all the patients were seen in the follow-up clinic approximately three weeks after the onset of illness. At this time each patient was re-examined, and blood was drawn for follow-up streptococcus MG and cold hemagglutinin titers.

Examination of the flora of the nasopharynx has been reported to be a fairly reliable procedure in determining the causative agent of pneumonia in children.⁶ It should be remembered, however,

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

SCARLET-FEVER STREPTOCOCCUS ANTITOXIN

The Division of Biologic Laboratories of the Massachusetts Department of Public Health discontinued the production and distribution of scarlet-fever streptococcus antitoxin on August 10, when the small stock reached its expiration date. Owing to the small amount of the antitoxin used in recent years, it would be an economic loss for the Department to continue its manufacture.

REFRIGERATION STORAGE OF VACCINE

The following letter regarding refrigeration storage of vaccine is believed to be of interest to physicians:

Geoffrey Edsall, M D
Antitoxin and Vaccine Laboratory
Massachusetts Department of Public Health
Forest Hills, Massachusetts

Dear Dr Edsall:

I thought you might be interested to know that at the Brookline Friendly Society, where we vaccinate somewhat more than 125 children a year, we have, using the Massachusetts vaccine, which is obtained from the Laboratory on the same morning on which the vaccinations are administered, had a 100 per cent take on the first vaccination for four successive years—in a group totaling well over 500 children—without a miss. The ages range from six months to three years, most of them being in the age group from six months to one year. Your product and the methods of storage that you employ are certainly as nearly perfect as anything could be.

Incidentally, it is interesting to note that my batting average is very much lower here in the office, owing, I am sure, to the fact that we are not able to keep the vaccine constantly below freezing.

Very sincerely yours,

RICHARD C TEFFT, JR., M D

Boston

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The September schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Haverhill	September 7	William T. Green
Brockton	September 8	George W. Van Gorder
Lowell	September 9	Albert H. Brewster
Salem	September 12	Paul W. Hugenberger
Greenfield	September 12	Charles L. Sturdevant
Gardner	September 13	Carter R. Rowe
Worcester	September 16	John W. O'Meara
Springfield	September 20	Garry deN. Hough, Jr.
Pittsfield	September 21	Frank A. Slowick
Hyanis	September 22	Paul L. Norton
Fall River	September 26	David S. Grice

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

MISCELLANY

UNITED COMMUNITY SERVICES

Dr. Philip D. Bonnet, Massachusetts Memorial Hospitals, will head the Hospital Group of the Service Division in the Red Feather campaign of 1949. Dr. Bonnet has been affiliated with the Red Cross and other social agencies in Philadelphia, where, until 1948, he was hospital administrator of Lankenau Hospital.

CORRESPONDENCE

UNWARRANTED PUBLICITY

To the Editor: Unfortunately considerable publicity, even in professional circles, has been given to a recent newspaper release concerning tonsillectomies performed on five youngsters in one family at the Malden Hospital on the same morning by Dr. Joseph Gitter of Malden.

It is indeed unfortunate that a newspaper "human interest" story should be so exploited. The children were service patients, all on Aid to Dependent Children, the occasion, a T and A clinic. Dr. Gitter, acting in the charitable capacity of senior surgeon on service, was unaware that some of the patients on whom he was operating in the course of the morning were related.

Officially, the hospital only gave permission for a photograph at the door upon discharge, the balance of the information, including the surgeon's name, was secured by the usual enthusiastic newspaper men from the usual "un-named sources."

The Malden Hospital
Malden, Massachusetts

NOTICES

ANNOUNCEMENTS

Dr. Samuel Bachrach announces the removal of his office to the Medical Arts Building, 36 Pleasant Street, Worcester, Massachusetts.

Dr. William M. Downing announces the removal of his office from 1180 Beacon Street, Brookline, where he was associated with Dr. Clifford C. Franseen. He has associated himself with Drs. H. Irving Bixby and Milton E. Johnson, First National Bank Building, Attleboro, for the practice of general surgery.

Dr. William J. Halpin announces the removal of his office from 5 Luther Road, Medford, to 307 Winthrop Street, Medford.

Dr. Douglas A. Thom announces the removal of his office to 459 Marlboro Street, Boston.

MASSACHUSETTS DEPARTMENT OF MENTAL HEALTH POSTGRADUATE SEMINAR IN NEUROLOGY AND PSYCHIATRY

The Fifteenth Seminar in Neurology and Psychiatry will begin October 3, 1949, and will continue until May 19, 1950. It will consist of three separate courses running concurrently as follows:

Review Course in Basic Neurology and Psychiatry, 66 lectures, every Friday, 2:00 p.m. to 8:30 p.m. from October 7 to December 9, 1949, and from March 3, to May 19, 1950, at the Metropolitan State Hospital, 475 Trapelo Road, Waltham, Massachusetts.

Course in Social and Special Psychiatry, 36 lectures every Wednesday, 5:30 to 10:00 p.m. from October 19 to December 14, 1949, and from March 15 to May 10, 1950, at the Boston Psychopathic Hospital, 74 Fenwood Road, Boston, Massachusetts.

Course in Pediatric Neuropsychiatry (Child Psychiatry), 20 lectures, every Monday, 6:00 to 9:30 p.m. from October 3 to December 5, 1949, at the Walter E. Fernald State School, Waverley, Massachusetts.

All interested graduate physicians should apply before October 1, 1949, by writing to Dr. William C. Gaebler, Superintendent, Metropolitan State Hospital, Waltham, Massachusetts.

The applicants should indicate which of the three courses of the seminar they wish to attend. The registration is requested as a matter of courtesy to the institutions where courses are conducted, also as a convenience for the registrants who will thus receive the schedules and be notified if changes should become necessary during the year.

AUREOMYCIN IN THE TREATMENT OF PNEUMONIA IN INFANTS AND CHILDREN*

BENNETT OLSHAUER, M.D.,† SIDNEY ROSS, M.D.,‡ ADRIAN RECINOS, JR., M.D.,§ AND
ELLSWORTH TWIBLE, M.D.†

WASHINGTON, D. C.

AUREOMYCIN is an antibiotic derived from a strain of *Streptomyces aureofaciens*. The drug has been found to have a wide antibacterial spectrum against gram-positive and gram-negative organisms. In addition, it has been found to be effective against rickettsia as well as certain viruses, chiefly of the lymphogranuloma-venereum-psittacosis group.¹ In man, therapeutic doses up to 60 mg per kilogram of body weight per day given orally have not been associated with toxic manifestations except for occasional nausea, vomiting and diarrhea. These symptoms have been transient and do not contraindicate or prevent continuation of therapy.

Aureomycin is absorbed readily after oral administration, and the maximum rate of excretion in the urine occurs between four and eight hours after the dose.² Thus, an interval between doses of four to six hours can be considered optimum. The oral route is the preferable mode of administration. Intramuscular injection is accompanied by local pain and sometimes induration and tenderness. Aureomycin may be given intravenously, but this method of administration was not employed in our series.

A study to evaluate the efficacy of aureomycin in the treatment of pneumonia in infants and children was instituted in January, 1949. This investigation was prompted by the observation that the drug is effective against the bacteria most frequently responsible for pneumonia and by published reports of its value in the treatment of atypical viral pneumonia.^{3,4} It has been found that strains of pneumococcus, streptococcus and *Hae-*

mophilus influenzae are almost completely inhibited by aureomycin in concentrations of 1 microgm per cubic centimeter or less.⁵ Such a blood concentration is readily obtained with therapeutic doses of the drug. Recently, Schoenbach and Brver³ and Finland and his co-workers⁴ reported small series of cases of primary atypical pneumonia that responded well to aureomycin. This constitutes the first indication of any effective antibiotic agent in viral pneumonia, all previous therapy having been found to be ineffective.

Thus, aureomycin, because of its versatility, seems to be an extremely valuable agent in the treatment of pneumonia. A drug that is effective against both viruses and bacteria embraces a considerably larger antimicrobial range than either sulfadiazine or penicillin (or both combined) and should be effective against the vast majority of pneumonias encountered in the pediatric age group.

MATERIALS AND METHODS

In view of these considerations it was believed that aureomycin warranted a clinical trial. To this end, a special pneumonia ward was set up at the Children's Hospital. So far as possible consecutive patients who had clinical and roentgenologic evidence of pneumonia were treated with aureomycin on admission to the hospital. These patients either had not received previous therapy or had not been benefited by chemotherapy or antibiotics.

A uniform plan of study was employed in all cases, including nasopharyngeal and blood cultures, blood counts, x-ray examination of the chest, agglutinins for streptococcus MG and cold hemagglutinins at periodic intervals during the course of therapy. Nearly all the patients were seen in the follow-up clinic approximately three weeks after the onset of illness. At this time each patient was re-examined, and blood was drawn for follow-up streptococcus MG and cold hemagglutinin titers.

Examination of the flora of the nasopharynx has been reported to be a fairly reliable procedure in determining the causative agent of pneumonia in children.⁶ It should be remembered, however,

that isolation of an organism from the nasopharynx is, at best, only partial evidence that it is the organism responsible for the disease in the lower respiratory tract. In the opinion of Alexander et al.⁷ the presence of substantial numbers of pneumococci in the nasopharynx of a child with pneumonia is a reliable index that the patient has pneumococcal pneumonia. The presence of a beta-hemolytic streptococcus or *H. influenzae* as the sole or predominant organism is only probable evidence that it is the pathogen in the lower respiratory tract. However, the isolation of hemolytic *Staphylococcus aureus* has little or no significance in determining the etiologic agent in pneumonia since it is found so frequently in the nasopharynx of normal children. A positive blood culture, of course, is presumptive evidence of the responsible organism of an associated pneumonia.

Thirty-nine patients fulfilling the established diagnostic requirements of pneumonia were studied. Their ages ranged from three months to eleven years and were distributed as follows: 3 patients were less than six months of age, 3 between six and twelve months, 10 from one to two years, 12 between two and five years, and 11 from six to twelve years.

Of the 39 cases in this series, 30 were classified as bacterial and 9 as viral in origin (Table 1). A pneumococcus was isolated in 16 of the 30 cases of bacterial pneumonia and a beta-hemolytic streptococcus in 2. *Staph. aureus* was cultured from the blood of an infant with a severe bilateral bronchopneumonia. The organisms cultured from the naso-

TABLE 1 Classification of 39 Cases of Pneumonia

Primary atypical	9

pharynx of the 11 unclassified patients represented the normal nasopharyngeal flora, including *Staph. aureus*, *Staph. albus*, *Streptococcus viridans* and *Neisseria catarrhalis*. The mere presence of these organisms in the upper respiratory passage was not considered sufficient to indict them as the causative agents of the pneumonia. However, the clinical manifestations together with the x-ray findings and leukocytosis were compatible with a diagnosis of bacterial pneumonia in this unclassified group.

In evaluating the efficacy of a new drug the severity of the illness should be taken into consideration. It was considered marked in 15 of 39 cases (38.4 per cent), moderate in 11 (28.2 per cent) and mild in 13 (33.4 per cent). Eight of the patients required oxygen. The children with bacterial pneu-

monia were in general more severely ill on admission than those with the viral cases.

The temperature of the patients in this series at the time of initiation of therapy ranged from 100.2 to 106°F. In 25 cases it was above 103°F. Patients in the bacterial group generally ran higher temperatures, 22 (73 per cent) having temperatures above 103°F at the time of admission.

White-cell counts are usually elevated in pneumonias of bacterial origin and normal or depressed in the viral types. In our cases all but 1 patient with bacterial pneumonias had white-cell counts above 10,000 on admission, and 6 of the 9 with viral pneumonias had counts below 10,000.

RESULTS

The therapeutic effect of aureomycin on the pneumonias of bacterial origin was quite favorable. The

over-all results (based principally on the rapidity of return to normal of clinical, roentgenologic and laboratory findings) were considered good in 24 cases, fair in 5, and poor in only 1. The results were particularly gratifying in the pneumococcal group, 14 of 16 patients showing a good response (Table 2). It is interesting that the unclassified bacterial pneumonias demonstrated a less dramatic response than the cases on which a specific organism was indicted.

In 15 (50 per cent of the 30 cases of bacterial pneumonia) the temperature returned to normal eighteen hours after initiation of aureomycin therapy. Four patients became afebrile in eighteen to thirty-six hours, and 9 maintained an elevated temperature from thirty-six to seventy-two hours. Two other patients had low-grade fevers beyond seventy-two hours, 1 for ninety-six and the other for one hundred and twenty hours. It is interesting that 9 of the 11 patients who maintained a temperature elevation beyond thirty-six hours had received aureomycin intramuscularly. In 2, a change from the intramuscular to the oral mode of administration produced a prompt defervescence within twelve to twenty-four hours.

Two infants with pneumococcal pneumonia had an associated pertussis and ran a protracted low-grade fever in spite of apparent early improvement of the pneumonia.

An evaluation of the effect of aureomycin on the pathogens of the nasopharynx was attempted. Cultures were obtained on the first, third and fifth hospital days on each patient. Of the 16 cases of pneumonia in which a pneumococcus was the predominant organism initially, 7 failed to grow out this pathogen on the second or subsequent cultures. In 4 others pneumococci were not demonstrable on the third culture. However, in 5 cases the organism was still present in the nasopharynx after five days of aureomycin therapy. There was no apparent correlation between the interval required for the elimination of the pathogen from the nasopharyngeal cultures and the over-all clinical improvement.

Serial white-cell counts were analyzed in the patients with bacterial pneumonia treated with aureomycin. In 71 per cent of the cases of pneumococcal pneumonia the white-cell count returned to normal (5000 to 10,000) within five days of the initiation of therapy. Six of 10 patients (60 per cent) with unclassified bacterial pneumonia showed an equally prompt drop to normal after aureomycin was started. In general the decline in the white-cell count was more rapid in children who were given the drug by mouth than in those who received it intramuscularly.

Each of the patients had an x-ray examination of the chest on the day of admission. Follow-up films were taken on all but 1 child and the majority were examined roentgenologically three or more times. A strict evaluation of the effect of aureomycin on the lesion radiologically was not possible because of the slight discrepancy in the intervals between films among the patients in the series. However for purposes of classification, the patients were arbitrarily divided into those who showed appreciable resolution by x-ray study in seven days or less and those in whom there was little or no change in that time. There was evidence of considerable resolution of the inflammatory process within seven days in 23 of 30 patients with bacterial pneumonia. A rather striking difference was noted in the roentgenologic results in the patients with bacterial pneumonia treated orally and in those treated intramuscularly. Sixteen of the 17 cases of pneumonias treated orally resolved appreciably within seven days whereas only 7 of 13 cases treated intramuscularly had shown resolution by x-ray examination in that time.

TREATMENT OF BACTERIAL PNEUMONIAS

The pertinent data of the 30 cases in the bacterial group are summarized in Table 3. The following 4 cases serve to illustrate the course of the various types of bacterial pneumonia treated with aureomycin.

S. L., a 7-year-old Negro, contracted a respiratory infection about 1 week before admission. For 2 days before entry he complained of pain in the left side of the chest that was ag-

gravated by breathing. Associated symptoms included cough, headache, malaise and fever.

Physical examination revealed an acutely ill child with rapid, grunting respirations. The temperature was 103°F. The pharynx and tonsils were reddened, and there were dullness and diminished breath sounds over the left lower portion of the chest posteriorly. The white-cell count was 27,700, with 84 per cent neutrophils. Pneumococci and beta-hemolytic streptococci were cultured from the nasopharynx and a blood culture was sterile. X-ray examination of the chest revealed an area of density in the medial two thirds of the lower left portion of the chest. The clinical course and other pertinent data are shown in Figure 1.

Shortly after admission aureomycin therapy was initiated in a dose of 250 mg orally every 4 hours. The temperature dropped rapidly to normal eighteen hours after therapy was started, and concomitantly the patient showed a striking clinical response. Subsequent nasopharyngeal cultures failed

FIGURE 1. Clinical Course and Laboratory and X-Ray Findings in S. L.

to grow out any pneumococci. Therapy was discontinued on the sixth day after an uneventful recovery.

T. D., a 5-year-old boy, was admitted to the hospital with a respiratory infection accompanied by cough of 3 days' duration. On the day before entry he became worse, with rapid respirations, a more severe nonproductive cough, pain in the left side of the chest, listlessness and anorexia.

Physical examination revealed a moderately ill, dyspneic child with a temperature of 102°F. There was dullness to percussion, and the breath sounds were diminished over the left side of the chest posteriorly.

The white-cell count was 18,500 with 75 per cent neutrophils. A blood culture was sterile. Beta-hemolytic streptococci were cultured from the nasopharynx. X-ray study of the chest revealed an area of opacity involving most of the left lower lobe and considerable infiltration throughout the right side of the chest. The course and other pertinent data are shown in Figure 2.

Aureomycin therapy was instituted shortly after admission in a dosage of 250 mg orally every 4 hours. Within 16 hours of admission the patient was afebrile and appeared much improved. The abnormal chest signs cleared gradually, and on the 6th hospital day there was x-ray evidence of complete resolution. The drug was discontinued after 5 days, and on the 6th hospital day the child was discharged after an uneventful convalescence.

V. F., a 10-week-old Negro infant, was well until 3 days before admission, when she began to cough and had a high fever and difficulty in breathing. These symptoms increased in severity until the time of hospitalization.

Physical examination disclosed an acutely ill, dyspneic infant with a temperature of 104.8°F, a pulse of 200 and respirations of 120 per minute. There were coarse and crepitant rales at both bases. The white-cell count was 26,000, with 49 per cent neutrophils and a predominance of immature

The patient was placed in an oxygen tent, and aureomycin was administered intramuscularly in a dosage of 10 mg every 8 hours. The infant improved rapidly, and in 12 hours was afebrile and out of oxygen. Except for slight rises in temperature on the 2nd and 4th hospital days, recovery was un-

prove after forty-eight hours of oral aureomycin. Penicillin and aureomycin were then given in combination, and the patient slowly improved, the temperature gradually returning to

aureomycin in this case was somewhat complicated. However, it is our impression that the drug exerted little or no salutary effect on the course of the illness.

Physical examination disclosed an acutely ill, dyspneic infant with a temperature of 104.8°F, a pulse of 200 and respirations of 120 per minute. There were coarse and crepitant rales at both bases. The white-cell count was 26,000, with 49 per cent neutrophils and a predominance of immature

The patient was placed in an oxygen tent, and aureomycin was administered intramuscularly in a dosage of 10 mg every 8 hours. The infant improved rapidly, and in 12 hours was afebrile and out of oxygen. Except for slight rises in temperature on the 2nd and 4th hospital days, recovery was un-

forms. Hemolytic *Staph. aureus* was cultured from the blood, and nonhemolytic *Staph. aureus* and pneumococcus were isolated from the nasopharynx. X-ray study of the chest revealed a disseminated bronchopneumonia. The course and other data are shown in Figure 3.

eventful. Subsequent blood cultures were negative, and aureomycin was discontinued after 8 days.

The patient in the bacterial group who was considered not to have benefited by aureo-

appears some two to four weeks after the onset of the illness these procedures have diagnostic value only in retrospect.

The rationale for a trial of aureomycin in atypical viral pneumonia rests on somewhat tenuous ground in view of the lack of precise etiologic data regarding the nature of the disease. It is known that the drug is particularly effective against some viruses, principally of the psittacosis-lymphogranuloma-venereum group. However, against the viruses of influenza A and B aureomycin has been found to exert no inhibitory effect *in vitro*. With the demonstrated ineffectiveness of penicillin and sulfonamide in atypical viral pneumonia it was considered worth while to treat a series of these patients as part of our investigation of the general efficacy of aureomycin in pneumonias in children. Nine cases appeared to fall into the category of atypical viral pneumonia. In the 5 cases that fulfilled all the criteria including serologic confirmation, the age range was two and a half to eleven years. The temperatures varied from 101 to 105°F. The illness was classified as severe in 1 case, moderate in 2 and mild in 2. None of the patients required oxygen.

Nasopharyngeal cultures consistently failed to reveal any pathogens. The white-cell counts varied from 7000 to 11 000. Four of the 5 patients had cold agglutinin titers ranging from 1:64 to 1:2048, whereas the streptococcus MG titers ranged be-

bodies noted in atypical pneumonias, a drop in titer was usually observed in the bacterial group during the second and third weeks. This has been reported previously by Young.⁹

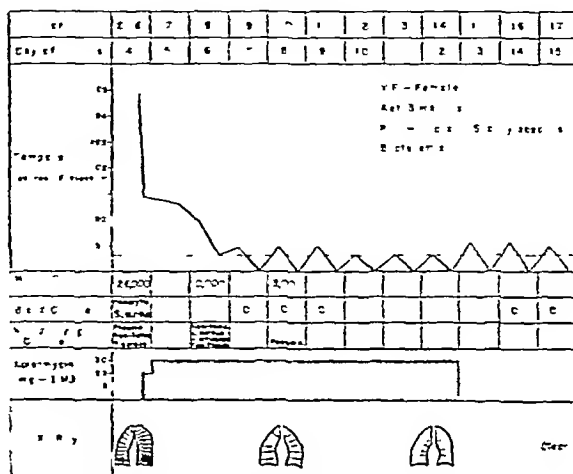

FIGURE 7. Clinical Course and Laboratory and X-Ray Findings in 1 F.

Four of the 5 patients had had previous therapy without apparent benefit. Penicillin in therapeutic doses had been tried for at least three days, and in 2 cases chemotherapy had been used in addition.

TABLE 4 (Continued)

CASE No.	MAXIMUM WHITE CELL COUNT	PREVIOUS THERAPY	AUREOMYCIN THERAPY			RESULTS
			DAY INITIATED	DOSE (kg 12 hr)	TOTAL DURATION (days)	
1	~ 900	Penicillin	9	30.0	6	Patient afebrile in 36 hr; recovery uneventful. x-ray evidence of clearing in 8 days.

tween 1:20 and 1:640. It should be pointed out that 4 patients with bacterial pneumonia had titers of cold agglutinins above 1:64 at the time of admission. However, in contrast to the rising anti-

Aureomycin therapy was instituted from four to nine days after the onset of illness. Four of the patients showed a favorable response and became afebrile thirty-six hours after therapy was started.

TREATMENT OF VIRAL PNEUMONIA

The diagnosis of primary atypical pneumonia is a difficult one, and the clinical picture, especially in infants and children, is often confusing. The

and a superimposed bacterial invader. Such cases of mixed infections are peculiarly indigenous to the pediatric age group. Furthermore, the hypothesis has been advanced by some investigators that primary atypical pneumonia may be caused by the synergistic action of bacteria and some unknown virus.⁸

Arbitrarily, the diagnosis of atypical viral pneumonia in our series was predicated on the history of cough, fever and physical and roentgenologic demonstration of pulmonary involvement, together with such laboratory aids as significant cold hemagglutination and streptococcus MG titers with normal white-cell counts. In a negative sense, the absence of pathogens from the nasopharynx as well as the lack of an adequate response to sulfadiazine or penicillin, or both, constituted additional evidence of a viral pneumonia.

Regarding the serologic phenomena associated with viral pneumonia, Horsfall⁸ reported that 55 per cent of cases will show a positive cold hemagglutination reaction in a significant titer of 1:40 or above within two to four weeks of the onset of the illness. This investigator has also shown that streptococcal MG agglutinins in titers of 1:20 or above appear within the third to the fifth week in 50 per cent of cases of viral pneumonia. Unfortunately, this investigation was performed primarily on adults. Whether infants and children show the same serologic response has not been conclusively

FIGURE 2. Clinical Course and Laboratory and X-Ray Findings in T. D.

disease varies widely in its clinical manifestations and severity of symptoms. The first indication that a case of pneumonia may be due to a viral agent

TABLE 4. Summary of 9 Cases of Viral Pneumonia Treated with Aureomycin

†Oral administration

is frequently the failure to respond to antibiotics or chemotherapy. Not infrequently, the clinical picture is further complicated by the presence of a mixed infection consisting of both a viral agent

demonstrated since there is a paucity of well controlled studies in the literature. It should be noted that in view of the fact that confirmation of the diagnosis of viral pneumonia from serologic studies

agglutinins on admission were negative, however, on the 21st day of illness a titer of 1:2048 was demonstrable. Streptococcus MIG titer, which was 1:10 on admission, had risen to 1:640 on the 21st day. Roentgenograms revealed an area of homogenous density involving the entire right upper lobe. A repeat film 1 week later showed a gradual decrease in the opacity. The clinical course and other data are shown in Figure 5.

Aureomycin was started in a dosage of 500 mg every 4 hours by mouth for 3 days and was then reduced to 250 mg every 4 hours. The patient gradually improved, the temperature falling by lysis over a 5-day period with daily elevations. The toxicity subsided slowly over the same period, but on physical examination there was little change.

It is difficult to attribute any beneficial effect to aureomycin in this case. It was believed that a spontaneous remission was the more likely explanation for this child's slow improvement.

DOSAGE AND MODE OF ADMINISTRATION

Aureomycin was administered both orally and intramuscularly in this series. Oral medication alone was given to 25 patients. Nine received the drug intramuscularly, and 5 received it by both routes (but not simultaneously).

Whenever possible, the drug was administered in capsules. In the younger patients who were unable to swallow capsules the contents were emptied, and one of the following vehicles was used (depending on the likes and dislikes of the child): chocolate syrup, cherry syrup, applesauce, strained pears, lemon juice, orange juice, chocolate milk and jello. For the most part both infants and children accepted the aureomycin in spite of its disagreeable taste.

The daily dose in the patients with bacterial pneumonias who were given oral medication ranged from 40 to 100 mg per kilogram of body weight per day, with an average of 63.5 mg. The patients with viral pneumonias received 25 to 65 mg per kilogram of body weight per day, with an average of 45.5 mg. It should be pointed out that the latter group was composed largely of older children. No special attempt was made to calculate a precise dose of the drug on a weight basis. The drug was given orally in divided doses at an interval of four to six hours. The intramuscular dosage varied from 3.0 to 12.0 mg per kilogram per day, with an average of 6.5 mg, the drug being administered at eight-hour intervals.

Aureomycin exhibited no untoward reactions aside from those referable to gastrointestinal irritation. The triad of nausea, vomiting and diarrhea occurred in 2 patients, whereas occasional vomiting without diarrhea was observed in 5.

In the determination of the time that elapsed before the patients became afebrile, a significant correlation was observed between the rapidity of defervescence and the mode of drug administration. Of the 13 infants and children who received intramuscular injection of aureomycin, 4 had a temperature drop to normal in less than thirty-six hours, and the temperature in 9 became normal after thirty-

six hours. In comparison, 22 of the 26 orally treated patients had a normal temperature in less than thirty-six hours, whereas only 4 cases required more than thirty-six hours. Several of the infants treated by the intramuscular route showed tender, indurated buttocks, and this may have been a factor in the persistence of fever. It was our impression that the oral mode of administration of aureomycin was superior to the intramuscular in its clinical effect in this series, hence, the intramuscular route was discarded early in the study, and thereafter employed only when it was impossible to give the drug by mouth. It is well to point out, however, that comparable doses of the drug orally and intramuscularly were not used, and therefore any rigid comparison between the two modes of administration would be untenable. Larger doses of the drug intramuscularly were not employed primarily because of the greater severity of local reactions with increasing amounts of the drug.

SUMMARY

Aureomycin was used in the treatment of 39 cases of pneumonia in infants and children.

In the 30 cases of bacterial pneumonias treated with the drug, the results were considered good in 24, fair in 5 cases and poor in only 1. The results were particularly good in pneumococcal pneumonia. Twenty-eight of the thirty patients were afebrile within seventy-two hours of initiation of aureomycin therapy.

In the 9 cases of viral pneumonia treated with aureomycin, all but 1 case were considered to have been favorably affected by the drug although the response was somewhat less striking than that observed with bacterial pneumonia.

Aureomycin was found to be more effective clinically when given orally than when given intramuscularly.

No toxic effects were observed in this series except for the occasional occurrence of nausea, vomiting and diarrhea.

We are indebted to Sara Stevens, B.S., M.T., and Mrs. Sarah Gouge for their technical assistance, to Phyllis Allred, R.N., and Lucie Knies, R.N., for their help in the compilation of statistics and to Dr. Harold W. Bischoff for the diagrams.

Roentgenologically, however, the pneumonic process was found to resolve more slowly than in the cases of bacterial pneumonia. The fifth patient (who is described below in detail) required four and a half days for defervescence, and this case was regarded as a probable therapeutic failure.

Four other cases were classified as having a probable viral etiology. The diagnosis in this group was based on the fact that nasopharyngeal cultures showed only nonpathogens, a leukopenia was present and the patients had failed to respond to antibiotics or chemotherapy. However, serologic tests for cold agglutinins and streptococcus MG anti-

cultured from the nasopharynx. X-ray study of the chest revealed a diffuse infiltration throughout the entire right side of the chest suggestive of bronchopneumonia and an increase in bronchovascular markings throughout the left side of the chest. The cold agglutinin titer on admission was 1:4, however, on the 18th day, it had risen to 1:128 and on the 40th day, the titer was 1:256. The clinical course and other pertinent data are shown in Figure 4.

The patient was given 300,000 units of procaine penicillin in oil intramuscularly daily for 4 days. However, the temperature remained elevated, ranging from 102 to 104°F and there was no clinical improvement. Penicillin was discontinued, and on the 4th hospital day, aureomycin therapy was instituted, 100 mg was given orally every 2 hours for three doses and then every 4 hours for a total of 5.1 gm over a period of 6 days. Twelve hours after the institution of therapy the temperature returned to normal and remained so except for a transitory elevation to 100.6°F on the following day. The child improved rapidly, and the chest findings gradually returned to normal. Roentgenologically the lesion resolved rather slowly but finally cleared within 8 days.

The patient was discharged in good condition on the 16th hospital day. He remained well at home and was found to be in good health when seen in the follow-up clinic 3 weeks later.

The case of a patient with atypical virus pneumonia who failed to respond to aureomycin was as follows:

D L, a 9-year-old girl, was admitted to the hospital with a nonproductive cough of 7 days' duration accompanied by slight anorexia but little or no fever. When she became febrile 4 days later, sulfadiazine had been started, however, her toxicity had progressed, necessitating admission to another hospital. Combined penicillin and sulfadiazine administered over a 3-day period appeared to be of little benefit, and the patient was transferred to the Children's Hospital for aureomycin therapy.

Physical examination revealed an acutely ill girl with a temperature of 105°F orally and respirations of 35 per minute. Positive findings were limited to the chest, which showed

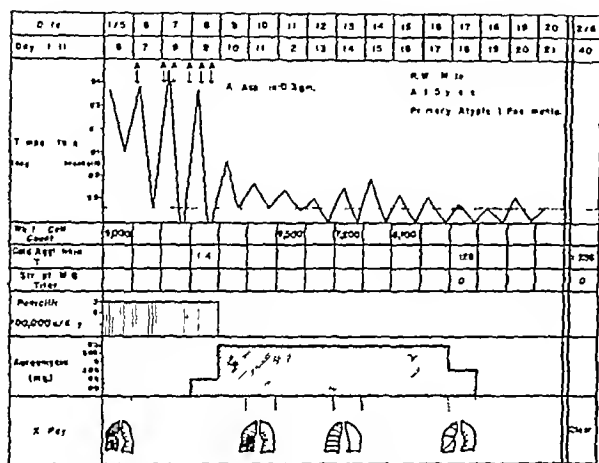

FIGURE 4 Clinical Course and Laboratory and X-Ray Findings in R W

bodies were negative. No attempts were made to isolate a viral agent. Each of these four cases showed a relatively good response to aureomycin therapy, with defervescence within thirty-six hours and clearing of the pneumonic process roentgenologically within five to eight days.

Details of the 9 cases with viral pneumonia are summarized in Table 4.

The following case is representative of the patients with atypical viral pneumonia who responded favorably.

R W, a five-year-old Negro boy, was well until 5 days before admission, when he began to cough. Two days later he began to vomit and had an elevation of temperature. These symptoms persisted until admission to the hospital.

Physical examination revealed an acutely ill boy with mild dyspnea. The temperature was 102.4°F. The tonsils were enlarged and injected. There were dullness and tubular breathing over the third to fifth interspaces anteriorly on the right, and dullness and increased breath sounds below the left scapula.

The white-cell count was 9000, with 80 per cent neutrophils. Blood cultures taken on the 1st and 2nd hospital days were sterile. A catarrhalis and hemolytic *Staph. albus* were

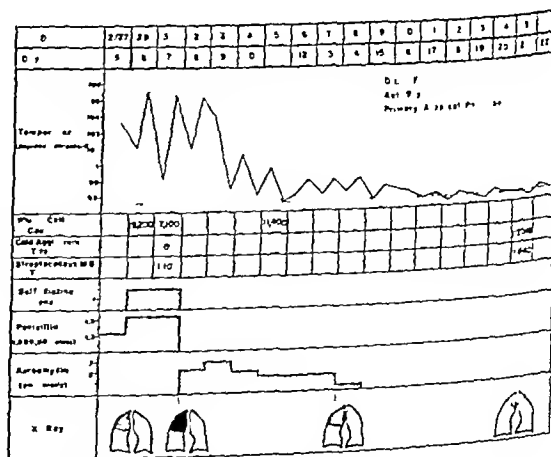

FIGURE 5 Clinical Course and Laboratory and X-Ray Findings in D L

a dullness and suppression of breath sounds over the right upper lobe.

Examination of the blood disclosed a red-cell count of 4,100,000, with a hemoglobin of 12.5 gm, and a white-cell of 7100, with 84 per cent neutrophils, 4 per cent of which were segmented. Urinalysis was essentially normal. A nasopharyngeal culture grew out hemolytic *Staph. aureus*. Cold

the midline it a severe attack was not treated promptly. Attacks were sometimes preceded by visual symptoms and were occasionally associated with nausea. Striking vascular phenomena were associated with the attack. These included generalized pallor before the headache and palpable pounding pulsation of peripheral arteries, particularly the right facial and right temporal arteries during the headache. The family history was positive for migraine and for gout.

The patient received no ergotamine tartrate until the fall of 1942. During the spring and summer of that year the frequency of migraine attacks increased from an average of one attack every 2 or 3 days until they were recurring daily. In July, 1942, an episode of status hemicranialis necessitated hospitalization. A ventriculogram performed at this time was normal. An electroencephalogram in 1942, and again in 1947, showed some minor abnormalities, more prominent on the left side (the side opposite the headache) but no localizing signs were present. Arteriography was not carried out during the 1942 admission but an arteriogram in 1947 was normal.

Figure 1 shows the average monthly requirement of ergotamine tartrate (Gynergen) required for the relief of headache from the time its use was initiated in 1942, until it was finally discontinued in 1947. When dihydroergotamine methylsulfate (DHE 45) was introduced, attempts were made to substitute this agent because of its lesser toxicity. It was found that 2 cc. (2 mg.) of dihydroergotamine could be substituted for each 1 cc. (0.5 mg.) of ergotamine, but that doses of dihydroergotamine adequate to relieve headache generally produced the same unpleasant side-effects as adequate doses of ergotamine—namely, some nausea and a single short episode of vomiting. Substitution of dihydroergotamine for ergotamine was also attempted several times during the period in which tolerance developed, and it became apparent that tolerance for the two agents was developing simultaneously and at the same rate. The headache was not relieved when 0.5 mg. of ergotamine was replaced by 0.2 mg. of ergonovine.

In the fall of 1942 when the patient first received ergotamine, the clinical response was most gratifying and was followed by a decrease in the frequency of attacks to one every 4 days. Later that year and in early 1943 attacks occurred even less often, but they increased in frequency with the return of warm weather. During the winter of 1943–1944, the patient enjoyed a 2 months' complete remission, but again the headaches recurred with warmer weather and they gradually increased in frequency and in severity.

Attacks were particularly severe during the summer of 1946. Beginning in May, 1946, headaches recurred daily. At first, they were well controlled by single daily injections of 0.5 mg. of ergotamine tartrate, but in July, 1946, larger single doses were required and the attacks recurred as frequently as twice or three times a day. Only on a single day from May, 1946, until 20 months later was headache ever completely absent. During this period and during the following months, the patient's peripheral vascular status was examined before each injection of ergotamine but no evidence of the development of peripheral vascular insufficiency was ever noted.

From July, 1946, until its use was interrupted in January, 1947, the amount of ergotamine required to control symptoms increased more or less continuously along the logarithmic curve shown in Figure 1. In the final weeks of its use, its efficacy became so slight that the administration of the required large intramuscular injections presented a real problem. Individual doses of 7 cc. (3.5 mg.) of ergotamine tartrate or of 12 cc. of dihydroergotamine methylsulfate (12.0 mg.—equivalent to 3.0 mg. of ergotamine) were given four times during the first 12 days of January, 1947, 10-cc. doses of dihydroergotamine were also given on eight occasions during this period. The largest total daily dose was given on January 10, 1947, when the patient received 13 cc. of ergotamine tartrate and 39 cc. of dihydroergotamine methylsulfate over a 24-hour period, a dosage of alkaloid equivalent to 16.5 mg. of ergotamine tartrate. During the entire month from December 12, 1946, until the use of ergot derivatives was discontinued on January 12, 1947 the patient received 531 cc. of ergotamine tartrate and 598 cc. of dihydroergotamine methylsulfate, administered intramuscularly in 115 individual doses.

Small doses of ergotamine tartrate, 0.5 mg. every 2nd or 3rd day, were again given during a period of attempted medical therapy in July and August, 1947, after external-

carotid ligations had proved unsuccessful. These doses were without effect on the headache. On October 1 a single intravenous infusion of 150 mg. of dihydroergotamine methylsulfate was given over a period of 6 hours. The procedure was uneventful for the first 5½ hours but was discontinued in the last ½ hour, when the patient complained of muscle cramps in both legs. This was accompanied by a fall in skin temperature and obliteration of the left dorsalis pedis pulse for 5 days. The left femoral and popliteal pulses were present throughout.

Since it became apparent not only that the headaches were more frequent but also that ergotamine was less effective, trials of many of the other current nonoperative treatments of migraine were undertaken. One hundred per cent oxygen gave partial relief in milder attacks but was the only agent to do so to a significant degree apart from narcotics and the

FIGURE 1 Average Monthly Requirement of Ergotamine Tartrate in a Patient with Unusually Severe Migraine

The dotted lines indicate periods for which the data are approximate. When supplementary DHE 45 (dihydroergotamine methylsulfate) was given, 4 mg. was considered the equivalent of 1 mg. of ergotamine tartrate. The dosage of 5 mg. a month in July and August, 1947, did not relieve headache.

vasoconstrictor analgesics of the ephedrine-benzedrine group. Attempts to uncover and to treat allergic hypersensitivity to histamine or environmental agents and a fifty-hour trial of psychoanalytic psychotherapy were likewise ineffective. No medical measures had any real degree of efficacy. Ligation of the right external carotid artery relieved pain partially for a short time, but the intensity of the pain began to increase 5 weeks postoperatively and soon had returned to its preoperative severity. Ligation of the left external carotid artery, ligation of the right middle meningeal artery and avulsion of the greater superficial petrosal nerve were entirely unsuccessful.

During this period, when ergotamine was losing its effectiveness, and subsequently when its use was stopped, and until the patient finally received neurosurgical relief, meperidine hydrochloride (Demerol) was required in increasing amounts to control pain, finally reaching a level of 3.0 gm. subcutaneously per day. It was discontinued without withdrawal symptoms after the pain was relieved.

The patient was completely relieved of headache by a section of the posterior root of the right trigeminal nerve performed at the Massachusetts General Hospital on December

DEVELOPMENT OF TOLERANCE TO ERGOT ALKALOIDS IN A PATIENT WITH UNUSUALLY SEVERE MIGRAINE*

WILLIAM Q. WOLFSON, M.D.† AND JOHN R. GRAHAM, M.D.‡

CHICAGO, ILLINOIS, AND BOSTON, MASSACHUSETTS

ERGOTAMINE tartrate (Ginerger) and the closely related dihydroergotamine methylsulfate (DHE 45) appear to be the most successful pharmacologic agents yet proposed for the treatment of migraine attacks. Careful study of the properties and liabilities of these agents is justified by the fact that they may become irreplaceable in the treatment of very severe migraine unless the risks of narcotic addiction or intracranial surgery are to be assumed. It seems worth while, therefore, to report a case in which tolerance to these drugs developed and to describe the heroic measures that subsequently became necessary to control the patient's pain.

When properly administered in adequate dosage, early in the headache phase of the attack ergotamine tartrate will rapidly terminate the attack in from 80 to 90 per cent of patients with migraine. The mechanism of its action depends upon its capacity to constrict dilated cranial arteries.¹ Dihydroergotamine is less effective in stopping headache, probably because it is a less vigorous cranial vasoconstrictor. When these drugs were compared, from 1 to 4 mg of dihydroergotamine was required to reproduce the relief of headache offered by 0.5 mg of ergotamine tartrate. Successful therapeutic amounts of these drugs often produce unpleasant toxic side-effects, such as nausea, vomiting, general lassitude, muscle cramps and transient vascular spasms. The problem, therefore, becomes one of finding, by trial and error, a dose of ergot alkaloid that will relieve headache with as few of these undesirable sequelae as possible. A few patients who tolerate ergotamine tartrate poorly will be relieved of headache by dihydroergotamine without disabling side reactions. Since the successful action of these drugs in relieving headache depends on their power of producing prolonged constriction of particular arteries, it is obvious that they should not be used in patients already suffering from obliterative vascular disease. Reports of several cases of ergotism that have occurred in patients receiving ergotamine for the relief of itching in jaundice^{2,4} suggest that the liver plays an important role in excreting or detoxifying this substance and that the presence of liver damage is a contraindication to its use. Ergotamine tartrate

should not be employed during pregnancy because of its oxytocic effect, and although dihydroergotamine is reputed to be less powerful in this respect, it should not be used in pregnancy until more is known of its effect on man.

If the contraindications listed above are observed, there seems to be no reason why parenteral doses equivalent to 1.0 cc (0.5 mg) of ergotamine tartrate should not be given as often as every other day to patients suffering from migraine. Daily, 1.0-cc (0.5 mg) doses of ergotamine have been taken with impunity over a period of several years by a few patients,⁵ but the reports of Cleveland⁶ and Isenstead⁷ suggest that, with doses of this frequency and amount, ergotism may possibly arise in otherwise healthy patients. Thus, if the daily administration of ergot derivatives becomes necessary, the patient should be forewarned and followed closely by the physician.

The minimum dose of ergotamine adequate to relieve headache, when once determined, ordinarily remains approximately constant from year to year even when the course of the disease requires frequently repeated administration. A patient of one of us has, for example, received ergotamine parenterally on an average of twelve to fifteen times each month over the past ten years. In 1938, this patient required 0.4 mg of ergotamine to relieve each migraine attack, but in 1948, 0.25 mg was equally effective although the headaches, if left untreated, apparently were not less severe. The unpleasant side-effects likewise usually remained just as active with the passage of time as they were with the first few doses. Most migraine sufferers, therefore, may count on the effectiveness both therapeutic and toxic, of ergot derivatives through the years.

In the case reported below, tolerance to both the therapeutic and toxic effects of ergotamine tartrate and dihydroergotamine methylsulfate developed rapidly after a long period of satisfactory response to normal dosage. The loss of effectiveness of these agents and the relative ineffectiveness of other medical measures, ultimately necessitated neurosurgical intervention to control pain. This appears to be the first reported case in which tolerance to ergot derivatives has developed.

CASE REPORT

A young woman had been in good health apart from severe migraine which had its onset in 1938 at the age of 20. The headache was right sided on all occasions, no headaches originated on the left side, although the pain spread across

‡Assistant in medicine, Harvard Medical School; assistant in medicine, Massachusetts General Hospital.

the midline if a severe attack was not treated promptly. Attacks were sometimes preceded by visual symptoms and were occasionally associated with nausea. Striking vascular phenomena were associated with the attack. These included generalized pallor before the headache and palpable pounding pulsation of peripheral arteries particularly the right facial and right temporal arteries, during the headache. The family history was positive for migraine and for gout.

The patient received no ergotamine tartrate until the fall of 1942. During the spring and summer of that year the frequency of migraine attacks increased from an average of one attack every 2 or 3 days until they were recurring daily. In July, 1942, an episode of status hemicranialis necessitated hospitalization. A ventriculogram performed at this time was normal. An electroencephalogram in 1942, and again in 1947, showed some minor abnormalities, more prominent on the left side (the side opposite the headache) but no localizing signs were present. Arteriography was not carried out during the 1942 admission but an arteriogram in 1947 was normal.

Figure 1 shows the average monthly requirement of ergotamine tartrate (Givnergen) required for the relief of headache from the time its use was initiated in 1942, until it was finally discontinued in 1947. When dihydroergotamine methylsulfate (DHE 45) was introduced, attempts were made to substitute this agent because of its lesser toxicity. It was found that 2 cc (2 mg) of dihydroergotamine could be substituted for each 1 cc (0.5 mg) of ergotamine, but that doses of dihydroergotamine adequate to relieve headache generally produced the same unpleasant side-effects as adequate doses of ergotamine—namely, some nausea and a single short episode of vomiting. Substitution of dihydroergotamine for ergotamine was also attempted several times during the period in which tolerance developed, and it became apparent that tolerance for the two agents was developing simultaneously and at the same rate. The headache was not relieved when 0.5 mg of ergotamine was replaced by 0.2 mg of ergonovine.

In the fall of 1942, when the patient first received ergotamine, the clinical response was most gratifying, and was followed by a decrease in the frequency of attacks to one every 4 days. Later that year and in early 1943, attacks occurred even less often but they increased in frequency with the return of warm weather. During the winter of 1943-1944, the patient enjoyed a 2 months' complete remission but again the headaches recurred with warmer weather and they gradually increased in frequency and in severity.

Attacks were particularly severe during the summer of 1946. Beginning in May, 1946, headaches recurred daily. At first, they were well controlled by single daily injections of 0.5 mg of ergotamine tartrate, but in July, 1946, larger single doses were required and the attacks recurred as frequently as twice or three times a day. Only on a single day from May, 1946, until 20 months later was headache ever completely absent. During this period and during the following months the patient's peripheral vascular status was examined before each injection of ergotamine, but no evidence of the development of peripheral vascular insufficiency was ever noted.

From July, 1946, until its use was interrupted in January, 1947, the amount of ergotamine required to control symptoms increased more or less continuously along the logarithmic curve shown in Figure 1. In the final weeks of its use, its efficacy became so slight that the administration of the required large intramuscular injections presented a real problem. Individual doses of 7 cc (3.5 mg) of ergotamine tartrate or of 12 cc of dihydroergotamine methylsulfate (12.0 mg—equivalent to 3.0 mg of ergotamine) were given four times during the first 12 days of January, 1947, 10-cc. doses of dihydroergotamine were also given on eight occasions during this period. The largest total daily dose was given on January 10, 1947, when the patient received 15 cc of ergotamine tartrate and 39 cc of dihydroergotamine methylsulfate over a 24-hour period a dosage of alkaloid equivalent to 16 mg of ergotamine tartrate. During the entire month from December 12, 1946, until the use of ergot derivatives was discontinued on January 12, 1947 the patient received 351 cc. of ergotamine tartrate and 398 cc of dihydroergotamine methylsulfate, administered intramuscularly in 115 individual doses.

Small doses of ergotamine tartrate, 0.5 mg every 2nd or 3rd day, were again given during a period of attempted medical therapy in July and August, 1947, after external-

carotid ligations had proved unsuccessful. These doses were without effect on the headache. On October 1 a single intravenous infusion of 150 mg of dihydroergotamine methylsulfate was given over a period of 6 hours. The procedure was uneventful for the first 5½ hours but was discontinued in the last ½ hour, when the patient complained of muscle cramps in both legs. This was accompanied by a fall in skin temperature and obliteration of the left dorsalis pedis pulse for 3 days. The left femoral and popliteal pulses were present throughout.

Since it became apparent not only that the headaches were more frequent but also that ergotamine was less effective, trials of many of the other current nonoperative treatments of migraine were undertaken. One hundred per cent oxygen gave partial relief in milder attacks but was the only agent to do so to a significant degree apart from narcotics and the

FIGURE 1 Average Monthly Requirement of Ergotamine Tartrate in a Patient with Unusually Severe Migraine

The dotted lines indicate periods for which the data are approximate. When supplementary DHE 45 (dihydroergotamine methylsulfate) was given, 4 mg was considered the equivalent of 1 mg of ergotamine tartrate. The dosage of 5 mg a month in July and August, 1947, did not relieve headache.

vasoconstrictor analgesics of the ephedrine-benzedrine group. Attempts to uncover and to treat allergic hypersensitivity to histamine or environmental agents and a fifty-hour trial of psychoanalytic psychotherapy were likewise ineffective. No medical measures had any real degree of efficacy. Ligation of the right external carotid artery relieved pain partially for a short time, but the intensity of the pain began to increase 3 weeks postoperatively and soon had returned to its preoperative severity. Ligation of the left external carotid artery, ligation of the right middle meningeal artery and avulsion of the greater superficial petrosal nerve were entirely unsuccessful.

During this period, when ergotamine was losing its effectiveness, and subsequently when its use was stopped, and until the patient finally received neurosurgical relief, meperidine hydrochloride (Demerol) was required in increasing amounts to control pain, finally reaching a level of 3.0 gm subcutaneously per day. It was discontinued without withdrawal symptoms after the pain was relieved.

The patient was completely relieved of headache by a section of the posterior root of the right trigeminal nerve performed at the Massachusetts General Hospital on December

23, 1947, by Dr James C White. At the time of writing, she has been completely free of headache for over a year.

DISCUSSION

In the case reported above, a striking resistance to large doses of ergotamine tartrate developed. During the development of this refractory state, resistance to other ergot alkaloids occurred. Thus, at various points during the phase of developing tolerance, it was possible to show, by substitution of dihydroergotamine methylsulfate for ergotamine tartrate in a ratio of 4 mg to 1 mg, that dihydroergotamine was equally effective (or, later, ineffective). Under these conditions, dihydroergotamine did not appear significantly more or less toxic than ergotamine. A number of trials with ergonovine maleate showed that refractoriness extended to this substance as well.

Resistance to the toxic effects of ergotamine appeared to develop at a rate parallel to that at which resistance to the therapeutic action developed, which suggested that the drug was being inactivated rather than that the cranial arteries were becoming refractory. At all times, the dose of ergotamine or of dihydroergotamine necessary to relieve headache also induced some nausea and usually a brief episode of sudden vomiting. If the dose given was insufficient to relieve headache, nausea and vomiting generally did not occur.

It is not clear whether interruption of the use of ergot derivatives in January, 1947, was followed by any significant return of sensitivity. Certainly, normal sensitivity did not return, as shown by the ineffectiveness of 0.5 mg of ergotamine given every two or three days during the following summer. The vascular effects of the large dihydroergotamine methylsulfate infusion of October 1, 1947, suggest that there had been some return of sensitivity. This must have been slight, however, since the infusion was tolerated at a rate of 2.5 mg per hour for over five hours before any effects were noted.

SUMMARY

What appears to be the first reported case of the development of tolerance to ergot alkaloids by a patient with migraine is reported. After three and a half years of typically satisfactory clinical response to the usual doses of ergotamine tartrate, tolerance to this agent developed rapidly and extended to dihydroergotamine methylsulfate and to ergonovine maleate as well. Refractoriness to the emetic and vascular effects of these agents developed concurrently with tolerance to the therapeutic effect. Withdrawal was not followed by a return of normal sensitivity within nine months.

During the period in which tolerance developed, most other medical measures currently used in the treatment of migraine were given trials. None were significantly successful. Surgical section of both external carotid arteries, of the right middle meningeal and right temporal arteries and of the right greater superficial petrosal nerve were ineffective. Complete relief of headache was finally obtained by surgical section of the posterior root of the right trigeminal nerve.

We are indebted to Drs Walter C Alvarez, James C White and J H Means, who kindly reviewed the manuscript, and to Dr C Henze and Mr S M Fossel, of the Sandoz Chemical Works, New York City, who generously co-operated by supplying a large part of the dihydroergotamine methylsulfate used in the study of comparative resistance to various ergot derivatives.

LOCALIZED PRETIBIAL MYXEDEMA*

A Stigma of Hyperthyroidism

GORDON N. FRENCH, M.D.†

WEST ROXBURY, MASSACHUSETTS

THE term "myxedema" is frequently used as a synonym for "hypothyroidism." It is a matter of common experience, however, that the majority of patients with clinical hypothyroidism do not have either local or generalized mucinous changes in the skin. Local myxedema in euthyroid persons is a familiar entity to the dermatologist. Such lesions usually are not symmetrically placed and appear singly or multiply on the upper or lower extremities or on the trunk. Definite, local, myxedematous changes may also occur in patients with exophthalmic goiter. A few reviews¹⁻⁴ and scattered case reports⁵⁻²⁴ have appeared. The concurrence of hyperthyroidism and local myxedema is not coincidental since all reported cases have this association. When local circumscribed lesions of myxedema have been described in hyperthyroid patients, they have, with rare exceptions, always been bilateral on the lower legs.

The gross appearance of the skin lesion is characteristic. Elevated plaques or nodules of thickened skin are present, well demarcated from the surrounding normal skin. The involved area is darker than that around it and is often yellowish pink. The hair follicles are wide and deep, producing a "pigskin" appearance. On palpation, the lesion is firm and cool, and it does not pit on pressure. Although the anterior tibial regions are always involved, extensive lesions may surround the lower leg. Symptoms arising from these areas are few. Mild, tingling pruritus or numbness may occur. Patients often complain of the unsightliness of their legs. If a biopsy is made, clear white viscous material escapes from the incision.

Histologic section reveals little change in the epidermis. In the corium the fibroelastic tissues separate into individual strands between which is a homogeneous, mucin-staining material. Occasional spindle cells are seen in this matrix. Lymphocytic infiltration around some of the smaller blood vessels is present. Pillsbury and Stokes⁶ examined all types of local myxedema and found them histologically indistinguishable. Watson² used hyaluronidase to incubate biopsied skin in his 2 cases. He obtained equimolar fractions of two polysaccharides and concluded that the mucinous material was hyaluronic

acid, chondroitin sulfuric acid or mucotin sulfuric acid. He ran similar tests on normal pretibial skin and found much less of this substance.

The lesion appears at variable times, either concurrently with the developing exophthalmos and other thyrotoxic signs and symptoms or after incomplete ablation of the toxic thyroid gland. Hyperthyroidism may be recurrent. In 69 cases reviewed by Trotter and Eden¹ the lesions appeared before treatment of the hyperthyroidism in 32, after x-ray therapy in 2 and after subtotal thyroidectomy in 35. Of the last group, 11 first showed the skin lesion during a recurrence of thyrotoxicosis. In 3 cases reported by Nettetton and Mulvey⁷ lesions developed with a recurrence of thyrotoxicosis after operation—2 during postoperative hypothyroidism and 1 sixteen years after a second thyroid operation. In a collection of isolated case reports most lesions appeared either preoperatively or with the reappearance of toxicity after partial resection.

Once present, local pretibial myxedema runs a slow and unpredictable course. Dunhill⁸ saw clearing of the lesions in 6 of his 7 cases after partial thyroidectomy, but this has not been the experience of others. The established lesion is not influenced by thyroidectomy, iodine or thiouracil derivatives. Complete remissions, without evidence of change in thyroid status, occur in some cases. Excision of the involved skin was performed occasionally for a cosmetic effect.⁶ In all cases in which the status of the eyes was mentioned, exophthalmos had been present at some time.

The incidence of this syndrome cannot be stated with less than 100 cases reported. Trotter and Eden¹ found it in 3 per cent of 130 cases of hyperthyroidism. Isolated short case reports have recently appeared,¹¹⁻²⁴ most of them as a part of the proceedings of meetings of dermatologic societies that are not listed in the *Quarterly Cumulative Index Medicus*.

Various terminologies have been suggested. Cohen,⁴ in a recent review, proposed the term "myxedema circumscriptum thyrotoxicum." This suggests that the syndrome is a definite entity and indicates its nature.

CASE REPORT

H. I. B., a 27-year-old married Navy veteran, apparently well until October, 1945, had noted gradual onset of increased perspiration, progressive loss of weight, voracious appetite, emotional lability and prominence of the eyes. He continued to sleep well, had no gastrointestinal disturbances and carried

23, 1947, by Dr James C White. At the time of writing, she has been completely free of headache for over a year.

DISCUSSION

In the case reported above, a striking resistance to large doses of ergotamine tartrate developed. During the development of this refractory state, resistance to other ergot alkaloids occurred. Thus, at various points during the phase of developing tolerance, it was possible to show, by substitution of dihydroergotamine methylsulfate for ergotamine tartrate in a ratio of 4 mg to 1 mg, that dihydroergotamine was equally effective (or, later, ineffective). Under these conditions, dihydroergotamine did not appear significantly more or less toxic than ergotamine. A number of trials with ergonovine maleate showed that refractoriness extended to this substance as well.

Resistance to the toxic effects of ergotamine appeared to develop at a rate parallel to that at which resistance to the therapeutic action developed, which suggested that the drug was being inactivated rather than that the cranial arteries were becoming refractory. At all times, the dose of ergotamine or of dihydroergotamine necessary to relieve headache also induced some nausea and usually a brief episode of sudden vomiting. If the dose given was insufficient to relieve headache, nausea and vomiting generally did not occur.

It is not clear whether interruption of the use of ergot derivatives in January, 1947, was followed by any significant return of sensitivity. Certainly, normal sensitivity did not return, as shown by the ineffectiveness of 0.5 mg of ergotamine given every two or three days during the following summer. The vascular effects of the large dihydroergotamine methylsulfate infusion of October 1, 1947, suggest that there had been some return of sensitivity. This must have been slight, however, since the infusion was tolerated at a rate of 2.5 mg per hour for over five hours before any effects were noted.

SUMMARY

What appears to be the first reported case of the development of tolerance to ergot alkaloids by a patient with migraine is reported. After three and a half years of typically satisfactory clinical response to the usual doses of ergotamine tartrate, tolerance to this agent developed rapidly and extended to dihydroergotamine methylsulfate and to ergonovine maleate as well. Refractoriness to the emetic and vascular effects of these agents developed concurrently with tolerance to the therapeutic effect. Withdrawal was not followed by a return of normal sensitivity within nine months.

During the period in which tolerance developed, most other medical measures currently used in the treatment of migraine were given trials. None were significantly successful. Surgical section of both external carotid arteries, of the right middle meningeal and right temporal arteries and of the right greater superficial petrosal nerve were ineffective. Complete relief of headache was finally obtained by surgical section of the posterior root of the right trigeminal nerve.

We are indebted to Drs Walter C Alvarez, James C White and J H Means, who kindly reviewed the manuscript, and to Dr C Henze and Mr S M Fossel, of the Sandoz Chemical Works, New York City, who generously co-operated by supplying a large part of the dihydroergotamine methylsulfate used in the study of comparative resistance to various ergot derivatives.

being increased in a few days to 300 mg a day. The basal metabolic rate steadily declined from +43 to +4 per cent in 30 days. During this period the patient underwent complete remission of all symptoms except those related to his exophthalmos and the pretibial myxedema. He gained weight

FIGURE 3 Extreme Exophthalmos of the Patient Whose Skin Lesions Are Illustrated in Figure 1. At the time the photograph was taken all other signs of thyrotoxicosis were well controlled with propylthiouracil.

regularly and was permitted to return to his on-the-job training as a color matcher in a paint factory. No changes in the eyes or in the leg lesions were noted at a follow-up examination 6 months later.

SUMMARY

The syndrome of exophthalmic goiter and bilateral pretibial myxedema is a distinct entity. This distribution of local myxedema is seen only in patients with past or present thyrotoxicosis. Histologically such skin lesions are indistinguishable from other types of myxedema.

A typical case of the syndrome is reported.

on with his duties. By late December he had lost 38 pounds of weight and was aware of a rapid heart beat. Examination at that time revealed an enlarged thyroid gland and the presence of exophthalmos. The basal metabolic rate was +55 per cent. The patient was started on Lugol's solution and was flown to the United States for definitive treatment. When his basal metabolic rate had fallen to +14 per cent a subtotal thyroidectomy was performed. The postoperative course was

for several weeks. The basal metabolic rate fell to +14 per cent but the drug was omitted because of a blood smear, which showed fewer than 50 neutrophils per cubic millimeter. For this reason the patient was admitted to the Veterans Administration Hospital in April, 1948.

Physical examination revealed a well developed and well nourished man in no distress but restless, constantly moving his hands and body. Under the right sternomastoid muscle was a firm mass, 5 by 5 cm., which moved with swallowing and appeared to be thyroid tissue. No thyroid gland was palpated on the left. Marked bilateral exophthalmos was present (Fig 3), and the lids could not be closed. Pupillary reaction was normal, and fundoscopic examination was negative. The heart was not enlarged, a regular sinus rhythm and a soft apical blowing systolic murmur were present. A fine tremor of the outstretched fingers was noted. Over each shin (Fig 1) were raised plaques, sharply demarcated, erythematous but not pitting. The hair follicles were wide and deep, the skin elsewhere was normal.

The blood pressure was 120/84, with a moderate tachycardia.

The blood serologic findings were negative, and a complete blood count was normal. The total serum cholesterol was

FIGURE 1 Lesions of Circumscribed Pretibial Myxedema

stormy. For several weeks he lost the sight of his right eye and had much impaired vision of the left. Although the eyes became exceedingly prominent he had no pain. Gradually the eyesight returned to its previous value, but exophthalmos continued. In March, 1946, he was sent East with the basal metabolic rate at +6 per cent. During the next 14 months he convalesced at the United States Naval Hospital at Chelsea, Massachusetts. There was a complete remission of all toxic symptoms, except exophthalmos, and he was discharged from the service.

At the time of his transfer to Chelsea the patient first noticed elevated, pink, painless areas of skin over the shins (Fig 1). They gradually increased in area but changed little if any in the months prior to admission to the Veterans Administration Hospital. A biopsy of one of the skin lesions was made at the Naval Hospital and reported as showing typical myxedema (Fig 2).

In the fall of 1947 the patient noted a return of his former toxic symptoms, including a weight loss of 14 pounds despite a large appetite. The basal metabolic rate at this time was +37 per cent. He was given propylthiouracil, 100 mg a day,

FIGURE 2 Photomicrograph of a Skin Biopsy Taken from a Pretibial Lesion of the Same Patient (The Slide was Kindly Lent for this Purpose by the United States Naval Hospital, Chelsea, Massachusetts)

161 mg, with esters of 73 mg per centimeter. A urinalysis was negative, with a specific gravity of 1.030. Subsequent white-cell counts were 7900 and 8400, with 65 per cent and 55 per cent neutrophils respectively. X-ray examination of the chest was negative. An electrocardiogram was normal except for low T waves in Lead V₆.

The patient remained afebrile. After preliminary studies he was given 200 mg of propylthiouracil a day, the dosage

SUMMARY AND CONCLUSION

Formulas before and after bacterial contamination were tested by four methods of processing

Steam pressure at 15 lb for five minutes gave adequate protection in all cases but demonstrated

MEDICAL PROGRESS

GASTROINTESTINAL ALLERGY*

FRANZ J INGELFINGER, MD,† FRANCIS C LOWELL, MD,‡ AND WILLIAM FRANKLIN, MD‡

BOSTON

GASTROINTESTINAL allergy is a diagnosis frequently entertained occasionally evaluated and rarely established It offers to its enthusiastic supporters, a reasonable explanation for many obscure abdominal complaints To the skeptical, it frequently appears as a specious and unwarranted diagnosis Although these conflicting views cannot be resolved on the basis of existing knowledge, the present status of gastrointestinal allergy is examined in this review with the hope of separating the well founded from the hypothetical

The term includes reactions occurring in the sensitized gastrointestinal tract as a result of contact with an allergen, whether the allergen is an ingested food or reaches the gut after inhalation or injection

Although foods are considered to be the most important cause of such reactions food allergy should be distinguished from gastrointestinal allergy Food allergy includes any allergic reaction due to an ingested food, whether the reacting site is in the gut or elsewhere

The number of gastrointestinal complaints that have been ascribed to allergy make up a formidable list, which includes heartburn, epigastric pressure, fullness, bloating, belching, nausea, vomiting, distention, aches, cramps and colics, constipation, diarrhea, fecal mucus, blood in stools and even jaundice¹⁻³ Allergy has also been suggested, at one time or another, as a cause of nearly all gastrointestinal diseases of obscure origin, particularly peptic ulcer⁴ and ulcerative colitis⁵⁻⁷ To summarize each of the articles supporting allergy as a cause of gastrointestinal disorders would present the reader with a tedious sequence of detail that, red

COMPARATIVE STUDY OF FORMULA PROCESSING FOR OBSTETRIC NURSERIES*

JOSEPH C MERRIAM, M.D.,† AND C G TEDESCHI, M.D.‡

FRAMINGHAM, MASSACHUSETTS

OUTBREAKS of diarrhea of the newborn in hospital nurseries have in recent years caused a great deal of needed emphasis on improving the technic of nursery care and of formula preparation. To study this entire problem the American Academy of Pediatrics set up a committee on the fetus and newborn infant, and this committee has in turn created subcommittees in various states.

The committee for Massachusetts¹ made specific recommendation taken from the New York Sanitary

its advance toward the maximum. Exposure continues for 15 minutes, no longer, after which the steam is turned off and the door opened immediately. The usual 15-17 pounds pressure should be maintained in the jacket of the sterilizer.

Step 2 Remove formulas from sterilizer and allow to cool at room temperature for approximately one to two hours. Finally, transfer formulas to refrigerator maintained at a temperature of 20° to 36°F where they remain until feeding time.

Since this procedure was at variance with the recommendation of the Massachusetts Committee on the Fetus and Newborn Infant, a question was raised about the future policy of the hospital regarding formula processing. It was consequently decided that a comparative study be made of the three alternative methods suggested by the Committee and the method directed by the American Sterilizer Company.

Two types of formula were tested, both of which were in current use in the hospital. One consisted of commercial evaporated milk, karo and water, and the other was identical except for the substitution of Grade A milk with 2 per cent fat content. These two formulas were tested in all four ways, both before and after contamination with pathogenic organisms. The bacterial counts were made according to the standard "American method" for milk analysis. Transplants were made in suitable

Code for the guidance of hospitals in formula preparation. This recommendation is as follows:

Formulae and other fluids offered to newborn infants in hospitals or child caring institutions, or in maternity hospitals or maternity homes shall be poured into individual feeding bottles at the time of preparation, and a nipple shall be attached to each bottle and covered with a cap. The entire product shall be then subjected to terminal heating by steam under pressure at not less than 15 pounds for not less than 5 minutes, or at a pressure of not less than 6 pounds for not less than 10 minutes, or by flowing steam at a temperature of not less than 100°C (212°F) for not less than 30 minutes.

At the time this recommendation appeared, the hospital where the studies given below were made, was preparing the formulas in accordance with the directions published by the American Sterilizer Company,² whose apparatus³ the hospital was using. These directions were as follows:

Terminal Disinfection of Formulas

Step 1 Following preparation, the formulas are immediately placed in sterilizer and disinfected by non-pressure steam for 15 minutes at 180°-200°F. The period of exposure is timed when the thermometer indicated 180°F in

CLINICAL OBSERVATIONS

Since gastrointestinal allergy includes a wide variety of complaints and exhibits no characteristic syndrome, the diagnosis cannot be made on the basis of symptoms *per se*. The majority of those who believe in the prevalence of gastrointestinal allergy consequently depend upon an apparent relation between the ingestion of a suspected food and the subsequent onset of symptoms. To some, the patient's say-so is sufficient. Thus, Andresen² believes that many medical mistakes have been made when the physician ignores a patient's observation that his symptoms follow the ingestion of certain foods, and in studying the chronology of allergic symptoms Alvarez and Hinshaw¹⁵ considered it sufficient to select their subjects on the basis that these patients "knew that the ingestion of certain foods regularly caused distress." In the opinion of others,^{19,22} the patient's incrimination of specific foods must be accepted with caution.

Even if the patient has correctly identified a certain food as the cause of his gastrointestinal symptoms, this correlation does not prove the existence of gastrointestinal allergy. Food intolerances of other origin must be considered.²⁰ Assuming that allergy does play a role, the gastrointestinal manifestations are not necessarily primary but could conceivably stem from an allergic reaction taking place elsewhere in the body. For example, gastrointestinal symptoms of all types might be caused by the intensely disagreeable sensations associated with the induction of severe asthma following the ingestion of certain foods.²³

Corroboration of impressions gained from the patient's history is frequently sought by the giving or withholding of the suspected food. If symptoms are invariably precipitated when a certain food is eaten, or conversely if they disappear on elimination diets, the culpability of the food seems to be demonstrated. Procedures of this type have consequently been used in many clinical studies that have attempted to establish the diagnosis of gastrointestinal allergy. Although the rationale of various elimination or provocative diets is similar, the technics of applying these measures vary in the hands of different allergists. The details of dietary tests are well expounded in the writings of Rowe,²² Vaughan,²⁴ Randolph,²⁵ and Rinkel.²⁶

Three major difficulties beset the diagnosis of gastrointestinal allergy as made by correlating symptoms with the eating of certain foods. In the first place, any patient's response is influenced by subjective attitudes that are difficult to exclude. Secondly, the attributes of gastrointestinal allergy are so all-inclusive that it emerges as a hazy entity with ill defined margins. Finally, neither the execution nor the interpretation of dietary tests is easy. These difficulties may now be considered in more detail.

Many physicians, aware of the emotional and situational forces that condition man's attitude toward food, accept the patient's incrimination of specific foods with reservation. Representing this point of view, Metzger²⁷ writes "If a fear or fixed idea concerning roses or goldenrod can, and apparently does precipitate a condition which is or resembles hay fever, why then is it not logical to assume that definite fears of needles, milk, and a host of other things react in the same way?" Phobias and fixed ideas are common in the neurotic." Results obtained by elimination or provocative diets may also be compromised by uncontrolled factors. Precipitation of symptoms by administration of a food to which the patient believes himself sensitive involves psychic factors sufficiently powerful to complicate the whole test. The dominant influence that such factors may exert has been demonstrated by Wolf²⁸ who showed that even the well established pharmacologic effects of a drug like atropine can be inhibited or reversed by the patient's attitude and expectations. Similarly, the apparent success of an elimination diet is hard to differentiate from the success any regimen may enjoy in the treatment of functional disorders, particularly if the regimen embodies considerable dietetic ritual and is administered by an enthusiastic physician who obviously has the patient's welfare at heart.

A fair evaluation of the effect of elimination diets in the therapy of organic disease poses comparable difficulties. In treating chronic ulcerative colitis, for example, careful observers^{6,7} insist upon removing from the diet foods that they believe play an allergenic and etiologic role. In their opinion, milk is a prime offender. Yet equally experienced physicians do not hesitate to use milk as a staple in their dietary management of ulcerative colitis. As long as ulcerative colitis remains a disease of obscure etiology, responding with approximately equal but incomplete success to a number of conflicting regimens, the etiologic implication of any therapeutic principle must be accepted with caution unless a specific relation between treatment and response is undeniable. For similar reasons, the beneficial effects claimed for elimination diets in the treatment of peptic ulcer^{4,9} are hard to evaluate.

When testing patients with foods to which sensitivity is suspected, one may reduce psychic factors by giving the test substance under carefully controlled conditions that prevent the patient from knowing, by sight, taste, texture, smell or any other means, what food is being given. The possibility of error in the diagnosis of gastrointestinal allergy is underscored by our experience with patients who are "clinically" sensitive to common foods but who failed to manifest any gastrointestinal symptoms whatever upon ingesting the suspected substances.²⁰ A twenty-year-old girl for example, stated that she could not eat fish because it caused vomiting and asthma, even getting near a fish market caused

would confuse rather than clarify the subject. In many reports, the material presented is insufficient, either to confirm or to discount whatever causative role is assigned to allergy. It appears preferable, therefore, to emphasize the methods used to demonstrate and diagnose allergic reactions of the gastrointestinal tract rather than to list opinions that are frequently conflicting. The measures used to demonstrate gastrointestinal allergy fall into three major categories: experimental studies, clinical observation and laboratory tests.

EXPERIMENTAL STUDIES

Experimental procedures do not provide conclusive evidence for the spontaneous occurrence of allergic reactions in the human gastrointestinal tract, but they do indicate that the gut, animal or human, may be the site of an allergic reaction causing recognizable local changes or disorders of function.

In sensitized dogs and rabbits, gastric ulcers were produced by Shapiro and Ivy⁸ after the injection of the antigen into the gastric mucosa. Ulcers in the stomach and duodenum were likewise caused in dogs by Friesen et al.¹⁰ using a special technique. An antiserum prepared against five antigens was injected into the gastric or duodenal wall or into the left gastric artery to induce local passive sensitization to the five antigens. Each of these was then injected into the systemic circulation on successive days to produce repeated allergic reactions in the sensitized area. Local edema without cellular reaction or eosinophilic infiltration was readily produced and was most marked two to six hours after injection of an antigen. Ulcers developed in some animals but were more frequent when the injections of antigen were associated with the administration of histamine in beeswax.

Although highly artificial, these experiments show that marked allergic reactions similar to those occurring elsewhere, notably the skin, may be produced in the gastrointestinal tract of animals. The circumstances in these experiments differ from those obtaining clinically in that injection was used for both sensitization and to elicit the allergic response. Experiments in guinea pigs have shown that systemic anaphylactic sensitization and the appearance of circulating antibody may follow ingestion of certain foods, such as milk¹¹ and egg white.¹² Sensitization arises, presumably, because the ingested antigen is absorbed into the circulation. In studies with egg white¹² prolonged feeding finally led to apparent failure of the antigen to traverse the gastrointestinal barrier. The antibody titer, having risen during the early feedings, fell during continued feeding, but quickly rose again when egg white was given by injection. The parallel between these observations and the well known tendency of children to outgrow clinically recognizable food

allergies is obvious. Leaving the more remote implications of these studies aside, there is clear evidence that the experimental animal may develop antibody and systemic anaphylactic sensitivity to antigens taken by mouth. However, these observations do not bear directly on gastrointestinal allergy because changes in the gastrointestinal tract itself were not seen. Furthermore, the circumstances of the experiments were again artificial because the antigens fed the animals were not normal constituents of the diet.

A closer experimental approach to the clinical aspects of gastrointestinal allergy is to be found in the work of Walzer and his co-workers.¹³⁻¹⁴ They injected serum obtained from a subject highly sensitive to peanut into the skin of the arm and into the mucosa of the rectum¹³ and the intestine in patients with ileostomy and colostomy.¹⁴ Introduction of peanut into the lumen of the bowel gave rise to edema at the sensitized sites in the skin and intestine at nearly the same time. Reactions in both sites also occurred when the peanut antigen was applied only to the sensitized site in the rectum or intestine. They considered that absorbed allergen reaching the sensitized site by way of the blood stream was primarily responsible for the reaction.

It was noted that, on rectal administration of the antigen, the edema at the sensitized (rectal) site began to develop slowly. This reaction preceded the lighting up of the control site on the skin by as much as six minutes. With the appearance and development of the cutaneous reactions the edema and erythema at the rectal site became more intense and rapidly reached its height.

They concluded that the local reaction "may be induced by antigen which is in direct contact with it or by absorbed antigen which reaches it via the circulation or by both."¹⁵

To these observations may be added the rare cases of abdominal pain, cramps, or diarrhea following overdosage during treatment of asthma or hay fever with injections of allergenic extracts. Especially significant is the much more frequent occurrence of nausea, vomiting, cramps, and diarrhea in persons being treated with pollen extracts by mouth.¹⁶⁻¹⁷ In these cases gastrointestinal symptoms were closely correlated with the administration of the allergen. Although the allergic nature of these symptoms need hardly be doubted, control studies were not done to rule out nonspecific irritation of the bowel.

These observations lead to the conclusion that under suitable circumstances marked allergic reactions may occur in the gastrointestinal tract, that systemic sensitization may be produced by ingestion of an allergen, and finally that the gastrointestinal mucosa may be sensitized with skin-sensitizing antibody (allergic reagin) and will react with edema on contact with the allergen, especially if this reaches the site by way of the blood stream.

doubted allergic background Bockus⁴³ believes that "Anxiety and tensional states, psychoneuroses, neurosis, vegetative and endocrinal disturbances, dietary and hygienic faults, and organic diseases account for abdominal symptoms in allergic persons much more commonly than do allergic reactions per se" Hence, a personal or family history of symptoms suggesting allergy does not appear to be a very reliable criterion when the role of allergy in either functional or organic gastrointestinal disorders is considered.^{4 5 44}

At times, gastrointestinal disorders are part of a syndrome originally described by Willan⁴⁵ ("purpura associated with violent vomiting, excruciating pain in the bowels, and anasarca swelling of the legs, thighs, and hands") but now often referred to as the Schönlein-Henoch syndrome. Attacks of this type were described in 29 patients by Osler⁴⁶⁻⁵⁰ visceral symptoms were usually associated with erythema, urticaria, angioedema, or purpura, but an occasional attack consisted of purely gastrointestinal disorders. Of the many patients with Schönlein-Henoch syndrome that have been reported since Osler's description, a few have been subjected to operation because of symptoms suggesting an acute condition of the abdomen. Abdominal pain in these cases must have been striking, but the operative findings have been inconstant. At times, the intestine has been edematous,⁴⁸ more often hemorrhagic,⁵¹ but frequently its appearance has been normal.⁵² Because some of the features of the Schönlein-Henoch syndrome resemble serum sickness, Osler⁵⁰ wrote, in typical style, "Before long the anaphylactic key will unlock the mystery of these cases." This suggestion has been readily accepted as an established fact, and Osler's cases are frequently cited as examples of gastrointestinal allergy.

Although Osler⁴⁶ stated that "the attack bears no relation whatever to food," several subsequent reports have ascribed this syndrome to food allergy.^{19 53-59} In some of these cases specific allergies may actually have been responsible for the Schönlein-Henoch syndrome. However, in most cases the relation of the symptoms to the alleged food allergen is not clear-cut. The interval between ingestion of the food and onset of symptoms ranges when given from fifteen minutes to nine days, in many cases the follow-up period appears inadequate, and in not a single case was the food given in a manner such that the patient was unaware of its nature.

Davis,⁶⁰ in reporting 44 cases of Schönlein-Henoch syndrome, did not consider food, drugs or other known allergens as the cause but emphasized that the attack frequently followed a hemolytic streptococcus infection. Similar observations were made by Gairdner,⁶¹ who, on the basis of his own cases and a review of the literature, suggested that the syndrome is linked clinically, pathologically and

etiologically with acute nephritis, rheumatic fever and polyarteritis nodosa. The syndrome of purpura, urticaria and gastrointestinal symptoms, it is apparent, may be a manifestation of hypersensitivity, but evidence that it is caused by ingestion of allergenic foods is inconclusive.

In a number of cases suffering from abdominal pains believed to be allergic in origin, an injection of epinephrine has been followed by relief within thirty minutes. This effect has been held to substantiate the allergic nature of the complaint.^{52 62} That epinephrine might alleviate gastrointestinal allergy as it relieves asthma and urticaria is a reasonable hypothesis. On the other hand, a sympathomimetic agent like epinephrine may be transiently spasmolytic as well. Relief of nonallergic symptoms by epinephrine is a possibility that detracts from its use as a therapeutic test in the diagnosis of abdominal allergy.

In summary, the diagnosis of gastrointestinal allergy by clinical means depends principally upon the patient's incrimination of specific foods, the effect of trial diets and association of the gastrointestinal complaints with manifestations usually believed to be allergic. Analysis of these criteria reveals them as quite unsatisfactory. The reliability of trial diets, theoretically the best of these diagnostic measures, is impaired by the expectations and the attitudes of the patient and by difficulties in execution and interpretation, but most of all by the vague nature of gastrointestinal allergy itself. A clear-cut, if tentative, definition of what constitutes gastrointestinal allergy must be made before the clinical diagnosis of this condition can achieve precision.

(To be concluded)

these symptoms. Skin reactions to fish were strongly positive. However, a freshly prepared fish extract, also causing a marked skin reaction of the immediate type, was introduced into the stomach by stomach tube in a manner to prevent the patient from knowing that fish was being introduced. No symptoms occurred, and there was no change in the stomach or small intestine recognizable by fluoroscopy. Furthermore, no delayed symptoms occurred.

If gastrointestinal allergy were a well defined entity with respect to etiology, chronologic sequence, reaction and reproducibility, the information obtained from the patient's history and test diets would be far more conclusive. If, for example, the ingestion of a certain amount of a specific food always produced the same symptoms within a certain interval, psychogenic and allergenic disorders could be differentiated quite satisfactorily. Unfortunately, as the following paragraphs indicate, the characteristics claimed for gastrointestinal allergy are extremely variable.

Alvarez and Hinchshaw¹⁵ state that an offending food may be recognized because symptoms regularly follow its ingestion within a period of one to twelve hours, and usually within three hours. Others, however, do not subscribe to this viewpoint and maintain that sensitivity to foodstuffs may be variable, intermittent, cumulative, nonquantitative and characterized by unpredictable time relations.^{2, 23, 29, 31} Some believe that a patient's sensitivity may vary because of climate, season, dietary habits, intercurrent infection, endocrine activity, emotional states or spontaneous immunologic fluctuations.^{6, 22, 32, 33} It has also been suggested that food may contain seasonal contaminants³³ (pollen in milk, for example), thereby explaining an inconsistent relation between symptoms and ingestion of the suspected agent. According to Vaughan,³⁴ a food may be eaten with impunity for days until a cumulative effect brings about symptoms. Others^{26, 35} believe just the opposite: if an allergenic food is eaten often enough, the allergy may be "masked," and a clear reaction may only be seen if ingestion of the food is preceded by a period of elimination. The interval between eating of a suspected food and ensuing symptoms may also be affected by the site of the sensitized gastrointestinal tissues and by the effects of digestion. The stomach, for example, might react within a few minutes of eating, but, unless the allergen is bloodborne, the colon might not be affected for forty-eight hours. The effects of digestion are disputed. Olmsted et al.³⁶ recommend as nonallergic a diet consisting principally of protein digests (amino acids and polypeptides), glucose, and vitamins. On the other hand, the products of protein digestion³⁶⁻³⁹ and even glucose²⁶ have been suggested as possible allergenic agents. If polypeptides, "proteoses,"⁴⁰ and "propeptans"⁴¹ are responsible for gastrointestinal allergic manifestations, the onset

of symptoms will obviously depend on the rate of digestion.

From a practical viewpoint, elimination diets are difficult to apply. Since allergy to minute quantities of food is believed possible,^{2, 26} the patient must exercise great care to avoid even the smallest quantity of any food, condiment or drink that is prohibited. Some patients are either too ignorant or too careless to follow such meticulous regimens. Others, dependent upon the processed foods so extensively used today, violate rules innocently. Even the cornstarch paste used in sealing cardboard food containers may, according to Randolph,⁴² contaminate the contents sufficiently to cause symptoms of gastrointestinal allergy. Whatever the reason, the success of an elimination diet is frequently threatened by its practical difficulties, particularly if a patient is believed to be sensitive to several foods.

Interpretation of many of the reported cases in which trial diets were applied to the diagnosis of gastrointestinal allergy is difficult because particulars are omitted. Although it is often stated that symptoms disappear after removal of a food, the duration of the symptom-free period may not be given. If symptoms persist during allergic management, their recurrence is usually attributed to unwitting ingestion of the incriminated food, evidence for which is sought by the most detailed and laborious history taking. That this may lead to serious error can be readily appreciated when it is realized that equally detailed histories may not be taken when the patient is well. Thus, repeated exposure to the allergen without development of symptoms is not excluded. On the other hand, when the patient eats the incriminated food with impunity, the discrepancy is often explained away by a number of assumptions, such as the existence of masked allergy, desensitization by repeated exposure, and refractory periods.

The tendency of more than one allergic manifestation to occur in patients with rhinitis, asthma, eczema and hives has led to the view that gastrointestinal symptoms occurring in such cases are often allergic in origin. However, the allergic nature of the reactions in the skin or respiratory tract is not always established beyond a reasonable doubt. In many cases of asthma, eczema and hives, demonstration of a causative allergen is difficult, and such manifestations are sometimes considered allergic chiefly because their clinical characteristics are similar to those in which the operation of an antigen-antibody reaction may be considered settled. Thus, a personal or family history of asthma, urticaria or eczema in a patient with gastrointestinal symptoms or abnormalities merely suggests an allergic tendency but in no way establishes the diagnosis of gastrointestinal allergy. Furthermore, gastrointestinal symptoms are so common that they may arise from a variety of causes even in patients with an un-

CASE 35341

PRESENTATION OF CASE

A twenty-two-year-old unemployed laborer entered the hospital because of visual difficulties.

The patient grew normally until the age of about thirteen years, when he realized that he was not as tall as other children. After fifteen years he stopped growing in height altogether. At the time of entry he measured 5 feet, 3 inches. His hat size was 7½ and his shoe size No. 8. He never developed axillary hair. He occasionally had erections and nocturnal emissions. Seven years before entry he first noticed that he had a squint, the left eye turning out. At the same time he began to have severe headaches which were usually "behind the eyes" and lasted from several hours to a day. They had become less frequent during the past year or two. Three years before entry the patient began to complain of inability to see well to either side. Because of this he bumped into things, particularly on the left. The patient did well in school and finished the second year of high school, after which he had to go to work. He supported himself as a laborer. His only complaint aside from his eyes was a chronically poor appetite.

Physical examination showed a patient who appeared more like an adolescent boy than a man of twenty-two years except for a peculiarly old facies with wrinkles about the eyes and mouth. His head was disproportionately large, and the extremities seemed too long for the body. The neck was short. Except for scanty growth of pubic hair, the skin was smooth and hairless. The skin of the distal phalanges was hard and shiny. The heart, lungs and abdomen were normal. The testes, penis and prostate were small. The left dorsalis pedis artery was not palpable. Both eyes were rather prominent. Vision was 20/20 on the right and 20/200 on the left. The left optic disk was pale, the right was normal. The left eye diverged about 25°, and the cranial nerves

were otherwise normal. The musculature was somewhat underdeveloped, but there was good strength. Sensation was normal.

The temperature, pulse and respirations were normal. The blood pressure was 90 systolic, 70 diastolic.

The fasting blood sugar was 67 mg per 100 cc. After 4.5 units of regular insulin, it was 26 mg per 100 cc in thirty minutes and 36 mg in one hour. At that point 0.4 cc of 1:1000 epinephrine was given intravenously. This was immediately followed by extreme anxiety, rapid pulse and pallor and a drop in blood pressure lasting about two minutes. The blood sugar curve was not affected and gradually returned to a level of 64 mg per 100 cc after a total of three hours.

The serum cholesterol was 320 mg and the cholesterol esters 241 mg per 100 cc.

The 17-ketosteroids in a twenty-four-hour urine sample were 0.4 mg.

The spinal fluid was normal with a pressure equivalent to 150 mm of water and a total protein of 26 mg per 100 cc. The basal metabolic rate was -22 per cent.

X-ray examination of the pelvis showed the epiphyses of the femoral heads to be closed. Those of the ilia were just closing. The epiphyses of the elbows, wrists and knees were closed but not fused. There was enlargement and destruction of the sella turcica. The posterior clinoids could not be traced but in their stead there was an area of calcification extending upward for half an inch. A pneumoencephalogram showed the bodies of the lateral ventricles to be elevated and obliterated along the lower margin. The third ventricle appeared to be displaced backward. The aqueduct was somewhat erect. There was no dilatation of the lateral ventricles. The intelligence quotient was 107, and psychometric tests did not reveal any definite indications of brain disease.

On the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. BERTRAM SELVERSTONE: Like so many patients who do not mature normally because of anterior hypopituitarism, this young man had apparently come to accept himself as he was—different from others but not alarmingly so. He complained chiefly of visual difficulties, a "neighborhood symptom." The stigmas of failure of the anterior pituitary body are, however, clear. A deficiency of growth hormone had apparently been present since before the age of thirteen, at which time he first noted his shortness of stature. Sparse pubic hair, absent axillary hair and small genitalia point to early hypogonadotropic eunuchoidism. The disproportionate limb length suggests an associated delayed closure of epiphyses and the roentgenograms of the long bones confirm this impression. Deficiency of thyroid

CASE 35341

PRESENTATION OF CASE

A twenty-two-year-old unemployed laborer entered the hospital because of visual difficulties.

The patient grew normally until the age of about thirteen years, when he realized that he was not as tall as other children. After fifteen years he stopped growing in height altogether. At the time of entry he measured 5 feet, 3 inches. His hat size was $7\frac{1}{8}$ and his shoe size No. 8. He never developed axillary hair. He occasionally had erections and nocturnal emissions. Seven years before entry he first noticed that he had a squint, the left eye turning out. At the same time he began to have severe headaches which were usually "behind the eyes" and lasted from several hours to a day. They had become less frequent during the past year or two. Three years before entry the patient began to complain of inability to see well to either side. Because of this he bumped into things, particularly on the left. The patient did well in school and finished the second year of high school, after which he had to go to work. He supported himself as a laborer. His only complaint aside from his eyes was a chronically poor appetite.

Physical examination showed a patient who appeared more like an adolescent boy than a man of twenty-two years except for a peculiarly old facies, with wrinkles about the eyes and mouth. His head was disproportionately large, and the extremities seemed too long for the body. The neck was short. Except for scanty growth of pubic hair, the skin was smooth and hairless. The skin of the distal phalanges was hard and shiny. The heart, lungs and abdomen were normal. The testes, penis and prostate were small. The left dorsalis pedis artery was not palpable. Both eyes were rather prominent. Vision was 20/20 on the right and 20/200 on the left. The left optic disk was pale; the right was normal. The left eye diverged about 25° , and the cranial nerves

were otherwise normal. The musculature was somewhat underdeveloped, but there was good strength. Sensation was normal.

The temperature, pulse and respirations were normal. The blood pressure was 90 systolic, 70 diastolic.

The fasting blood sugar was 67 mg per 100 cc. After 4.5 units of regular insulin, it was 26 mg per 100 cc in thirty minutes and 36 mg in one hour. At that point 0.4 cc of 1:1000 epinephrine was given intravenously. This was immediately followed by extreme anxiety, rapid pulse and pallor and a drop in blood pressure lasting about two minutes. The blood sugar curve was not affected and gradually returned to a level of 64 mg per 100 cc after a total of three hours.

The serum cholesterol was 320 mg and the cholesterol esters 241 mg per 100 cc.

The 17-ketosteroids in a twenty-four-hour urine sample were 0.4 mg.

The spinal fluid was normal with a pressure equivalent to 150 mm of water and a total protein of 26 mg per 100 cc. The basal metabolic rate was -22 per cent.

X-ray examination of the pelvis showed the epiphyses of the femoral heads to be closed. Those of the ilia were just closing. The epiphyses of the elbows, wrists and knees were closed but not fused. There was enlargement and destruction of the sella turcica. The posterior clinoids could not be traced but in their stead there was an area of calcification extending upward for half an inch. A pneumoencephalogram showed the bodies of the lateral ventricles to be elevated and obliterated along the lower margin. The third ventricle appeared to be displaced backward. The aqueduct was somewhat erect. There was no dilatation of the lateral ventricles. The intelligence quotient was 107, and psychometric tests did not reveal any definite indications of brain disease.

On the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. BERTRAM SELVERSTONE: Like so many patients who do not mature normally because of anterior hypopituitarism, this young man had apparently come to accept himself as he was—different from others but not alarmingly so. He complained chiefly of visual difficulties, a "neighborhood symptom." The stigmas of failure of the anterior pituitary body are, however, clear. A deficiency of growth hormone had apparently been present since before the age of thirteen, at which time he first noted his shortness of stature. Sparse pubic hair, absent axillary hair and small genitalia point to early hypogonadotropic eunuchoidism. The disproportionate limb length suggests an associated delayed closure of epiphyses, and the roentgenograms of the long bones confirm this impression. Deficiency of the thyroid

stimulation by thyrotropic hormone will explain the low basal metabolic rate and elevated serum cholesterol. There is evidence also of deficiency of the adrenocorticotrophic hormone, the low arterial pressure and increased sensitivity of the blood glucose concentration to the administration of a small dose of insulin are important in this connection. Presumably, a severe impairment of glycogen storage in the liver was present, as shown by the failure of the lowered blood glucose to rise when a large dose of epinephrine was administered. We may consider this anomaly of carbohydrate metabolism to be a manifestation of deficiency in glucocorticoids, resulting also from lack of adrenocorticotrophic hormone. The extremely low value for urinary 17-ketosteroids reflects the deficiency both in gonadotropic and in adrenocorticotrophic factors. I should not consider abnormal the extreme cardiovascular and emotional response that resulted from the intravenous administration of 0.4 cc of 1:1000 epinephrine. This was an unusually large intravenous dose and could well have produced these alarming symptoms in a normal person. The curious admixture of youth and senility in his appearance is a common feature of hypopituitarism. Perhaps Dr. Albright can tell us the precise endocrine basis of this phenomenon.

The manifestations that with respect to the pituitary body, we call "neighborhood symptoms" were apparently more important to the patient. It is not surprising that squint and headache were complained of for four years before he noted visual impairment, since an acuity of 20/20 was still present in the right eye at the time of admission. The headache is significant—it was not the bitemporal aching pain often present when the diaphragma sellae is stretched by an intrasellar tumor but was a pain "behind the eyes." This is suggestive of pressure on the tentorium, although pain may be referred to this region from other portions of the basal dura. The left external strabismus is suggestive of pressure on the oculomotor nerve although other manifestations of such pressure were not noted. Pressure from above, as by a herniated hippocampal gyrus, usually produces pupillary dilatation as a first sign of compression of this nerve against the free edge of the tentorium. The arrangement of fasciculi in the nerve is such that pressure from an anterior direction might well produce an early extraocular muscle weakness. Pressure on the third nerve at its entrance into the cavernous sinus, or even within the sinus, might also produce this picture. The patient complained for three years of inability to see well to either side, and apparently his symptoms were worse on the left side. The pale left optic disk, with 20/200 vision on the left, confirms the impression that this patient may have had originally a bitemporal hemianopsia, which later spread to include the macular field on the left. Unfortunately, objective determination of the visual fields is not mentioned in the case summary. All that we may say, however, that there was

evidence of chiasmal compression, more marked on the left side. That the lesion was only slowly progressive is suggested by the normal psychometric examination and normal cerebrospinal fluid pressure.

We have, then, a young man who presents evidence of a lesion of at least nine years' duration, involving the basal dura, optic chiasm and possibly the left oculomotor nerve. The anterior pituitary had been progressively compromised, without evidence of impairment of posterior pituitary function.

A number of lesions in the region of the sella turcica can produce a clinical picture with some of the features presented by this patient. Although two or three earlier cases appear in the literature, chromophobe pituitary adenomas are usually not manifest until after the age of fifteen years. They do not produce the suprasellar calcification mentioned in the description of the roentgenograms. Glioma of the optic chiasm could be considered also, but preservation of even 20/200 vision in the left eye and normal visual acuity in the right after so long a period would be most unusual. Then, too, a severe endocrine disturbance is most uncommon with such lesions. Meningioma of the tuberculum sellae may occur at twenty-two but would be most unusual at thirteen years, when symptoms were first noticed. Endocrine abnormalities are usually not a feature of this tumor and an elevation of cerebrospinal-fluid protein would probably have been noted. Arachnoiditis of the optic chiasm could produce visual changes such as those described, but pituitary dysfunction is not a feature of the disease and calcification, if it occurs, is in a position anterior to that described. Curiously enough, occasionally in obstructive hydrocephalus, the floor of the third ventricle may be ballooned downward sufficiently to produce chiasmal compression and pituitary hypofunction. The normal cerebrospinal-fluid pressure and the pneumoencephalographic findings effectively rule out such a disorder.

A variety of hamartomas may occur in the midline at the base of the brain. Cushing* reported, in 1912, a case of Osler's in which a teratoma the size of a golf ball was found in the interpeduncular fossa of a sixteen-year-old seamstress. Dermoids and lipomas may also be seen. The cholesterol deposits of Hand-Schüller-Christian's disease characteristically affect the neurohypophysis rather than the anterior lobe. Chordoma of the basisphenoid should also be mentioned. Chordomas usually run a briefer course, but one such lesion of eighteen years' duration has been reported. Much more extensive destruction of the base of the skull would probably have occurred during the nine years of this patient's story, and a nasopharyngeal mass would have been likely as well.

If we proceed now to a more detailed consideration of the roentgenographic findings, we are led to

*Cushing, H. *The Pituitary Body and Its Disorders*. 341 pp. Philadelphia: J. B. Lippincott Company, 1912. P. 43.

a more common clinical entity. The description of enlargement of the sella turcica with an area of calcification extending upward from the region of the absent posterior clinoids is that of the cystic or solid tumor of a Rathke-pouch remnant variously called craniopharyngioma or adamantinoma. Such calcification is seen in 70 to 85 per cent of these lesions. The term "destruction" is used also in describing the sella. If true destruction, as opposed to erosion by pressure, was present, we must consider also the carcinoma, which occasionally arises in such a lesion. The description of the pneumoencephalogram is consistent also with craniopharyngioma, an unusually large one, extending under the frontal lobes and probably adherent to mammillary bodies, midbrain and pons as well. I cannot be certain whether the lesion was primarily cystic ("suprasellar cyst") or solid. The former would offer a much more favorable prognosis.

CLINICAL DIAGNOSIS

Craniopharyngioma

DR SELVERSTONE'S DIAGNOSIS

Craniopharyngioma (adamantinoma) with secondary hypopituitarism

ANATOMICAL DIAGNOSIS

Suprasellar epidermal cyst

PATHOLOGICAL DISCUSSION

DR CHARLES S KUBIK. Operation by Dr William H Sweet disclosed a cystic suprasellar tumor with a dense, fibrous capsule and contents consisting of yellowish, avascular, soft solid, flaky material, which was removed by spoon and suction, leaving an "enormous" cystic cavity. The material appeared to be typical of epidermoid cyst, not only on gross inspection but also microscopically, consisting of faintly outlined epithelial cells and containing cholesterol crystals. The cyst wall, of which only a small piece was removed, was composed of dense connective tissue. Although no epithelial lining was included with the biopsy specimen, the character of the flaky material removed left little or no doubt that this was a cyst lined with epidermal cells, sometimes also known as "cholesteatoma" and "pearly tumor." The flaky material consists of accumulated desquamated epithelial cells.

Epidermoid cyst of the region of the chiasm is considerably less common than craniopharyngioma, but we have had 2 or more other cases. In at least 1 of them there was a homonymous hemianopsia, and the tumor was on one side, as in this case. They may occur in other parts of the cranium and cranial cavity—for example in the orbit, cerebellum, inter-cerebral fissure, temporal bone and other parts of the skull.

In this case the patient made a good recovery. His headache was relieved. The visual acuity of the left eye did not improve, and the homonymous hemianopsia persisted.

CASE 35342

PRESENTATION OF CASE

A seventy-year-old Irish housewife entered the hospital because of extreme weakness.

Five weeks prior to admission she noted the onset of excessive weakness and "tiredness." Shortly thereafter she began to suffer continuous dull, aching, nonradiating, epigastric pain unrelated to meals. This was associated with mild nausea and occasional vomiting without hematemesis. Vomitus either was watery and sour or contained undigested food, depending on time relation to previous meal. There was mild loss of appetite. No irregularity of bowel habit was noted and the stools were free of blood. Two weeks prior to admission the urine became "red," and the stools light in color. A physician made a diagnosis of "yellow jaundice" for which "white pills" were prescribed. Weakness was progressive and finally required hospital entry after "her knees suddenly gave way" as she was walking about her house. Consciousness was not lost during this episode, nor were there any other symptoms referable to the central nervous system. There had been a 20-pound weight loss during the preceding three months. Moderate generalized pruritus was a troublesome symptom from the onset of the present illness.

Twelve years before entry she developed an indolent ulcer on the second toe of the left foot. She was found to be mildly diabetic but was rapidly standardized with a daily dose of protamine zinc insulin of 36 units daily. The toe was amputated, and the pathological report was acute and chronic osteomyelitis. From that time on she attended the Out Patient Department sporadically. The diabetes remained under good control without significant alteration in insulin requirement.

Physical examination disclosed an extremely obese, deeply icteric woman able to lie comfortably, flat in bed. The body weight was 215 pounds. Numerous cutaneous excoriations were prominent, but there was no superficial lymphadenopathy. The heart and lungs were clear. Minimal tenderness without muscle guarding was elicited in the right upper quadrant of the abdomen. The liver edge was palpable 15 cm below the right midanterior costal margin "with the suggestion of another edge 5 cm above the liver border." Owing to the patient's obesity it was impossible to determine the character of the liver or to establish the presence or absence of nodules. There was a minimal rectocele, but no masses could be palpated on digital examination. There was no edema of the extremities,

and pulsations were palpable over the dorsalis pedis and popliteal arteries. The Achilles and patellar reflexes were not elicited, but the biceps reflexes were active and equal.

The blood pressure was 130 systolic, 58 diastolic. The temperature, pulse and respirations were normal.

The urine was acid and the specific gravity ranged from 1.008 to 1.016. There was a + to +++ test for albumin. The urine contained sugar (green) on only one occasion. Many granular casts and leukocytes were noted in the sediment. Bile tests were ++++ at all times, but the urinary urobilinogen was negative. Examination of the blood showed a red-cell count of 3,900,000, with a hemoglobin of 12 gm., and the white-cell count ranged from 15,000 to 22,000 with neutrophils ranging from 84 to 92 per cent. The stools were pale and guaiac positive on two occasions. The blood sugar was 237 mg. and the nonprotein nitrogen 66 mg. per 100 cc. The cephalin-flocculation test was + in 24 hours and ++ in forty-eight hours, the lipase was 2.5 cc. The total protein was 5.51 gm. per 100 cc., with 2.83 gm. of albumin and 2.68 gm. per 100 cc. of globulin. The van den Bergh reaction was 20 mg. per 100 cc. direct and 24 mg. per 100 cc. indirect. The prothrombin time was 16 seconds (control 15 seconds). The carbon dioxide was 21.6 milliequiv. per liter, the phosphorus was 4.9 mg. per 100 cc., and the alkaline phosphatase 43.0 units per 100 cc.

Adequate fluoroscopic study of the gastrointestinal tract was impossible because of the patient's size and debility. On routine films the right leaf of the diaphragm was higher than usual but the lung fields were clear. The esophagus contained a tube but was otherwise not remarkable. No localized disease was detected in the stomach. There was a suggestion of a filling defect measuring approximately 2.5 cm. on the medial aspect of the second portion of the duodenum. The duodenal loop, however, did not appear enlarged. The liver shadow appeared enlarged.

Following admission the patient had no complaints other than weakness. She tolerated a soft diet well for twenty-four hours but then began to vomit all food eaten. For this reason food was withheld, and parenteral feedings were employed. A gastric tube was passed and left in position in order to aspirate barium following the gastrointestinal series.

On the fourth hospital day she became disoriented. On the following day she became stuporous, but the diabetes was considered under fair control. Her course was one of rapid deterioration. Coma supervened on the following day, and death occurred twenty-four hours later. During the last day of life the temperature rose to 101°F, the pulse to 100, and the respirations to 25.

DIFFERENTIAL DIAGNOSIS

DR DANIEL S. ELLIS: As I read this case over, it seemed to me fairly easy to make a diagnosis that would explain most of the reported findings.

Let us, for the moment, consider this patient's diabetes. This was of twelve years' duration. Apparently it was mild, of the type seen in elderly people, and was easily controlled although she had one gangrenous toe, which was amputated. She could possibly have gone into diabetic coma during the last few days of her life. But had she done so, I am sure that we would have had laboratory and clinical evidence of it. Next let us consider infection. I cannot find any real evidence of a chronic suppurative process. It is true that she had a high white-cell count, with a high neutrophil count. She was afebrile until the end. There is nothing else in the record to suggest any chronic suppurative process unless, perhaps, one is going to say that she had chronic pyelonephritis.

I am left with the problem of deciding whether or not this patient had obstructive jaundice due to mechanical block in the extrahepatic biliary tree or diffuse parenchymal disease of the liver. I believe very strongly that her death was due to disease in her liver, yet there is little evidence to make a diagnosis of diffuse parenchymal disease in the nature of hepatitis, cirrhosis or yellow atrophy. The cephalin-flocculation test, which I would expect to have been +++ or ++++ if the jaundice and liver disease had been caused by hepatitis or cirrhosis, was normal. The fact that she had no urobilinogen in the urine, although she had plenty of bile present, is strongly in favor of an obstructive type of jaundice. In addition, the patient had itching of three months' duration. If that were on the basis of parenchymal liver disease, hepatitis, cirrhosis or biliary cirrhosis, almost surely there would have been other laboratory evidence of such a condition. One frequently sees itching as a presenting symptom in obstructive jaundice, or of disease involving the liver or extrahepatic biliary tree, long before jaundice supervenes. So we have several findings very strongly in favor of an obstructive process: the long history and itching, the high alkaline phosphatase, the light-colored stools, and the lack of urobilinogen in the urine.

The x-ray report mentions something in the second portion of the duodenum. This is, of course, one of the places that we want to look at, and a gastrointestinal series should be done on all patients with unexplained jaundice, even though they have not had nausea or vomiting or anything else to point to gastrointestinal disease.

Dr. Wyman, will you show the x-ray films? I would like to be sure that this woman had some significant finding in the second portion of the duodenum.

DR STANLEY M WYMAN The right leaf of the diaphragm is considerably elevated, and the liver appears considerably enlarged. The lung fields are not remarkable grossly. A gastrointestinal examination was done in the supine position only. I could not examine the esophagus because of the presence of a large tube, which one can see in the lower esophagus. The stomach itself was very large and contained retained fluid, but there was no evidence of gross intrinsic disease of the stomach. The duodenal loop was impossible to see well fluoroscopically, but there appeared to be a pressure defect of the second portion of the duodenum on its medial aspect, measuring perhaps 2.5 cm in diameter. This is seen on one film well, is only suggested on this second film and is inadequately seen on this third film.

DR ELLIS Anatomically, is that where the ampulla of Vater is or where the common duct lies going through the duodenal wall?

DR WYMAN I think this area is in or about the ampulla of Vater. I thought she had a tumor of the ampulla, or distal common duct, or else a non-opaque stone. Examination, of course, was not ideal.

DR ELLIS To tie in with Dr Wyman's findings, this woman had a positive guaiac reaction on the stools. The nausea and vomiting were not necessarily due to any lesion in the stomach or gastrointestinal tract. They may have been caused by the severe disease that I am assuming she had in the liver or in the biliary tract somewhere. There is nothing to suggest an increase in the width of the duodenal loop due to a carcinoma of the pancreas.

As Dr Wyman has told you, we have no evidence of intrinsic disease in the stomach itself.

I cannot make any case for an extremely fatty liver, other than the fact that she was obese. We are not told of any alcoholic history. One of the things that can cause this picture of deep jaundice, a sudden and progressive onset to fatal outcome, is an acute fatty alcoholic liver in which no normal cells, or practically none, are observed in histologic sections. The liver may be large, and the skin deep orange. The history may not suggest it at all. The laboratory tests at that time may be so equivocal and the process so relatively acute that they have not had a chance to reach the point where they would show evidence of parenchymal disease. This is just a possibility that I must think about and that must be ruled out. It would be of help to have had an aspiration biopsy from the liver. It might have revealed whether or not she had diffuse fatty infiltration of the liver or metastatic disease in the liver.

This patient may have had a pylephlebitis due to some focus of infection of which I am not aware. I will do no more than mention that as a possibility. I cannot rule out the presence of lymphomatous disease.

I really believe that this woman had metastatic carcinoma involving the liver. That is the one condition, or one of the conditions, that will give a tremendous liver and a high alkaline phosphatase. The question is: Where did the carcinoma come from? It could have come from the stomach. There is one suggestion that there was a mass on top of the mass of liver. It is pointed out in the protocol that the mass was felt 5 cm above the margin of the liver. One wonders if the mass was gall bladder and the upper mass was the liver edge. The x-ray studies do not indicate carcinoma of the stomach. Therefore, I cannot hold to that diagnosis.

Carcinoma of the head of the pancreas frequently metastasizes to the liver. It may metastasize to the porta hepatis, without metastasizing elsewhere, and cause obstructive jaundice. If this was such a case, I cannot explain the tremendous size of the liver reported.

Could this patient have had gallstone? She certainly could. If so, it was a silent stone and apparently in the common duct if the jaundice was due to it.

We are now left having to explain her death and her large liver. I would not think she had been sick long enough, or had jaundice long enough, to cause her death if all this was on the basis of simple obstruction. For that reason, I believe that this woman had a carcinoma of the biliary tract, probably in the common duct or ampulla of Vater, and that she had metastases all through the liver, producing hepatomegaly and leading to hepatic failure. Metastases in the liver frequently do not manifest themselves until the patient is almost in a terminal stage. I think that her sudden death was due to extensive involvement of the liver by cancer. The blood in the stools was probably on the basis of an ulcerative tumor of the common duct or the ampulla of Vater. In a certain number of cases, however, deeply jaundiced patients may have guaiac-positive stools without any ulcerative lesion.

The protocol reports albumin and granular casts and some cellular elements in the urine. This in a woman seventy years might simply be a finding that one frequently sees in an arteriosclerotic person who is extremely ill. I suppose, because of the large number of cellular elements, I have to say that there was some factor of pyelonephritis here, but I find it hard to say that that was any more than a concomitant finding and it did not play a part in the terminal episode.

Carcinoma of the biliary tract, probably arising in the common duct or ampulla, with metastases to the liver, was my first impression to explain this case. I still stick to it and am fully prepared to find out that something existed that I have not mentioned. The x-ray report of a deformity in the region of the ampulla leads me to exclude primary hepatoma as a possibility.

CLINICAL DIAGNOSIS

Carcinoma of ampulla of Vater

DR ELLIS'S DIAGNOSES

Carcinoma, biliary tract
 Extensive and diffuse metastases to liver
 Diabetes mellitus
 Generalized arteriosclerosis
 Arteriosclerotic kidneys — ? pyelonephritis

ANATOMICAL DIAGNOSES

Carcinoma of gall bladder
Thrombosis of hepatic and portal veins, neoplastic
Massive infarction of liver
 Intercapillary glomerulosclerosis
 Cholelithiasis
 Neurofibroma of esophagus
 Carcinoma of right breast

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Autopsy showed a liver filled with carcinoma as Dr Ellis had suspected. It took a little longer to clear up the question of the primary site. There was no tumor at the ampulla of Vater. There was a shallow benign peptic ulcer in the duodenum, which was probably responsible for the blood in the stools. The gall bladder was greatly enlarged and was obviously the edge that was clinically interpreted as liver, whereas the second "edge," 5 cm higher, was the true liver margin. There was a large stone impacted in the ampulla of the gall bladder, and the walls of the gall bladder showed papillary excrescences and one rather large necrotic mass that could have been inspissated secretion or totally necrotic tumor. There was no doubt that the carcinoma arose in the gall bladder.

One of the surprises of the autopsy was that the veins throughout the liver, both portal and hepatic, were extensively thrombosed. There was mas-

sive secondary infarction of liver substance. The thrombus from the hepatic vein had extended up into the inferior vena cava in a form that could be called Chiari's disease. These thrombi consisted in large part of fibrin and platelets but also had many tumor elements in them. Hepatomas, of course, commonly invade the hepatic vein. It is rare for a tumor arising in the gall bladder, as we are sure this one did, to do so, but it is not impossible.

We found a number of coincidental lesions. There was a small intraductal carcinoma of the right breast, which had not produced metastases. The esophagus contained a submucous neurofibroma of significant size, 1.5 by 3 cm, which had apparently produced no symptoms, and there was a colloid adenoma of the thyroid gland.

The patient was enormously obese and deeply jaundiced, and post-mortem examination was delayed for fourteen hours so that post-mortem decomposition was severe and microscopical sections are not of very much help. We did, however, think that we could recognize enough in the kidney to say that she had the Kimmelstiel-Wilson type of glomerular change that is so commonly seen in advanced diabetes. There was slight pyelonephritis. I do not believe either lesion was responsible for any significant symptoms and death was explained first by carcinoma and secondly by acute liver insufficiency and liver necrosis, dependent on a massive thrombosis of the veins throughout the liver substance.

DR ELLIS I think it is amazing how far cancer of the liver, especially metastatic, can go before it is recognized. I did not bring out the fact, as Dr Mallory has done, that the terminal episode is frequently due to some such processes as occurred here.

DR BENJAMIN CASTLEMAN How large was the liver?

DR MALLORY It weighed 3500 gm.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston 15, Massachusetts. Telephone KE 6-2094.

IMPROVED BLUE SHIELD BENEFITS

THE Blue Shield program in Massachusetts has undergone recent changes some of which will widen its scope and all of which should increase its value.

A surgical-obstetrical but nonmedical contract will be reissued to compete with the low-cost surgical-obstetrical contract now issued by commercial insurance companies. It is unfortunate that internists are at present excluded from participating in this part of the Blue Shield program, but in this instance price, and not benefits, is the determining factor.

Both the new surgical-obstetrical and the present medical-surgical-obstetrical contracts will be offered to nongroup subscribers who are not eligible for group enrollment. Two years ago contracts were offered to nongroup subscribers, but the difficulties toward which Blue Cross was at that time headed forced the suspension of nongroup enroll-

ment in both organizations. As of September 1, 1949 nongroup enrollments will be available to every healthy applicant in the Commonwealth.

A change in subscription rate will be rendered necessary by this new policy. The yearly subscription rate of \$29 per family has been found insufficient to cover the losses sustained on families in the nongroup and conversion categories. The conversion category consists of those subscribers who leave their place of employment, about half of whom allow their insurance to lapse. Many of the remainder retain their coverage because of the anticipation of medical care. Consequently the rate for these two categories only will go from \$29 to \$32 per year.

Certain clarifications have been made in the provisions of both surgical-obstetrical and medical-surgical-obstetrical contracts. Benefits will be provided for the care by a pediatrician of a premature baby weighing four and a half pounds or less. Benefits will not be provided for the circumcision of an infant during the first year of life, as such an operation is practically never a surgical necessity.

A member who uses private accommodations in a hospital when private accommodations are not medically necessary and ward accommodations are available, becomes thereby a limited or overincome member, subject to an additional charge by the attending physician. It is believed, however, that the profession should exercise extreme caution in availing itself of this provision.

A one-year waiting period will go into effect for nongroup members before benefits will be provided for care or treatment of any condition existing in any form on the effective date of the subscription agreement.

The best way to defeat compulsory health insurance is to render voluntary insurance more desirable. This the various medical-service plans of the country are successfully accomplishing.

"SING OUT SWEET LAND"

By action of the Council of the Massachusetts Medical Society taken at its annual meeting on May 25, the appointment of a co-ordinating committee to co-operate with the National Education

Campaign of the American Medical Association was confirmed. The committee, which has been functioning since April, is composed of the officers of the Society, the delegates to the American Medical Association, representatives from the committees on medical economics, legislation, public relations and the subcommittee on national legislation, the director of information and education, and the editor of the *Journal*. The chairman is Dr. Frank H. Lahey, former president of the American Medical Association.

The committee considers the time now appropriate to render an account of its activities as well as to offer its program for the future.

Of special importance has been the assembly that took place on May 1 at the Hotel Statler, to which each district society was invited to send ten per cent of its members. The attendance was estimated at six hundred and considerable enthusiasm for the campaign was evidenced.

A speaker's bureau has been established and some twenty physicians have given nearly three hundred talks before various lay groups. Editorial support has been elicited and numerous press and radio writers and commentators have supported the campaign to bring the Association's program before the public. Many lay groups have been active and a number of organizations have passed resolutions in support of the medical profession. Much literature has been distributed, and more is available at the Society headquarters.

Although the Government's campaign in favor of compulsory health insurance has been relatively inactive of late, the co-ordinating committee is planning its own future program. This is based largely on the activities of the district societies, most of which have not yet swung into satisfactory action, Franklin being a notable exception.

District co-ordinating committees must be set up where they are still lacking. Co-operation with the "Tell it to Twenty" division of the Massachusetts campaign must be strengthened, in order that a continuous flow of information to the list of twenty contacts made by each physician may make an informed group capable of substantial action and results at the proper time. Resolutions against compulsory national health insurance should

be adopted by every district society and auxiliary. Local press and radio committees should be organized and contact made with local professional groups. Lay speakers must be enlisted, and above all the district woman's auxiliaries must be utilized in the campaign.

If socialized medicine is to form the wedge for a socialized state, it shall not be for lack of an informed and intelligent opposition.

DONORA SMOG

OF THOSE few freedoms that remain to hunted man, the air he breathes has been considered as a fundamental right, common to all. Even the air, however, as the dweller in industrial areas well knows, may become as polluted by mechanical progress as are the water courses of the world's more advanced nations.

Uncontrolled (although largely controllable) smoke has been one of the by-products of the fiercely burning fires of industry, increasingly being shown to constitute a hazard to health as well as an offense to the eyes and a stench in the nostrils.

Especially spectacular were the conditions that prevailed for a short period last fall over Donora, Pennsylvania. Here, apparently as the result of static atmospheric conditions combined with the proximity of the American Steel and Wire Company zinc plant, a so-called "smog" descended over the city and presumably precipitated the deaths of twenty susceptible persons.

As a result of this episode the Public Health Service of the Federal Security Agency conducted a test in April to determine, if possible, the cause of the disaster. During the test the plant gradually resumed full production with no evidence of unfavorable conditions resulting. The assumption is that an unusual atmospheric state was necessary to trap in the valley of the Monongahela River the effluvium of the plant.

The knowledge is reassuring that lethal conditions will only occasionally result from the chance association of industrial production and bad weather. It is disturbing to realize that progress in public health must be made across the deserts and over the pol-

luted streams and through the poisoned air that man is himself creating

Perhaps out of the almost forgotten disaster at Donora will come something more tangible than the perpetuation of an accordion-pleated word

MOUSE TOWER

THE story, recently released, of Columbia's mouse dairy is another reminder of the unique relations that exist between mice and men. Rats and mice for better or for worse—but principally the latter—have exercised their influence over human affairs since rats and mice and men began

Hamelin had its experience with rats and learned too late that it pays to pay the piper. In the tenth century a singularly unworthy ecclesiastic, Bishop Hatto, having oppressed the peasantry of his fief and becoming annoyed at their protestations, shut them all into a barn, which he burned. Their squeals he likened to the squealing of mice.

As famine spread over the land a plague of rodents appeared to escape which Bishop Hatto fled to his well stocked tower on an island in the Rhine. The Rhine, as history has shown before and since proved no barrier to a determined invader. The mice crossed it, stormed the castle, and devoured the squealing bishop, presumably in some upper chamber.

Columbia's mouse tower in the College of Physicians and Surgeons, twelve years old and sixteen stories high, differs in its conception from that of Bishop Hatto.

At a cost of about \$10,000 a quart, two quarts have been obtained annually from several thousand mice each of which has been milked regularly (by suction), producing an average of 1 cc of milk per pregnancy.

The result of this costly dairy, however, the story of which is contained in a release from Columbia University has been a long forward step in the study of cancer. Certain strains of mice are peculiarly susceptible to a cancer of the breast that closely resembles the human form. The cancer virus has been isolated in the milk of these high-cancer-strain mice. This milk when introduced into the systems of other mice male or female, of low-cancer or high-

cancer strain, by ingestion or injection, gives rise to cancer in a high percentage of cases.

The destructive rodent has made another part payment on the debt it owes to humankind.

Dr Thomas Hooker was prosecuted in Canada, recently, on complaint of the College of Physicians and Surgeons, for practising physic without license, and fined £10 and costs. He had better come into New England where any body can practise medicine whether they understand it or not.

Boston M & S J, August 22 1849

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

ALLEN — Harold M. Allen, M.D., of Lawrence, died July 3. He was in his sixtieth year.

Dr. Allen received his degree from Tufts College Medical School in 1913. He was a fellow of the American Medical Association.

His widow, a son and a daughter survive.
